### THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. FREKE, A.B., M.B., M.R.I.A.

(Continued from page 132.)

#### PART II.—PRELIMINARY OBSERVATIONS.

MY second division of the subject which I have ventured to attempt to investigate is the following—namely, an inquiry into the nature of the mechanism of the human circulatory apparatus. Before we can clearly comprehend the nature of that mechanism—that is, in other words, before we can obtain a clear and comprehensive acquaintance with the true nature of the relation in which the several distinct component parts of that apparatus, regarded as separate and individual structures, stand towards each other while in the discharge of their respective physiological functions—that is, stand towards each other while collectively and in union fulfilling the end or design with which that apparatus as a whole has been constructed; before, I say, we can acquire a clear and satisfactory insight into the nature of that relationship, it would, as I regard it, be desirable, in the first place, to take a rapid and summary survey of the nature of the relative functions generally of the several distinct orders or classes of organized structure, which we have already seen generated in the animal world, with the design of giving development to the several distinct orders or classes of vital phenomena included under what are termed the phenomena of animal life. Let me be distinctly understood. It will, I say, as I regard it, be desirable, in the first place, to take a general survey of the nature of the relationship in which the various organized residual products, which we have already seen generated as the ultimate or final results of the regenerative process, stand towards each other while fulfilling the end or design with which those products have been generated; stand towards each other while conjointly or in union giving development to their respective physiological functions; in a word, stand towards each other while, as one harmonious whole, giving manifestation to the varied phenomena which constitute

what we designate "*animal life*." In other words, we are, as I regard it, called on, in the first place, to inquire—*What is the nature of the relation* which subsists between nervous tissue, vascular structure, muscular fibre, and cerebral matter, while those several residual products unitedly (that is, in union as a whole) are respectively giving development to what we term nervous phenomena, vascular action, muscular motion, and mental phenomena? *How* are those structures respectively related to each other while developing their respective physiological functions? *This*, I say, is the question which, in relation to the inquiries at present before us, should, as I regard it, in the first place, engage our attention.

Having attained to such knowledge—that is, having in the first instance acquired a general insight into the nature of that relationship, we should then, as I regard it, in the second place, proceed to the consideration of the following question—namely, *What are* the several organized structures or residual products which enter into the constitution and form the several distinct component parts of that apparatus known as the human circulatory system?

Should we be enabled to obtain a clear and satisfactory reply to each of the two foregoing inquiries, we shall, as I regard it, have acquired a clear and comprehensive acquaintance with the true nature of—the mechanism of the human circulatory apparatus.

Before engaging with me in the investigation of the former of the two foregoing inquiries, I would solicit of the reader, in the first place, to have clearly and distinctly before his mind the facts and relations which have as yet been ascertained with regard to the ultimate or final results of the regenerative process. In other words, I would beg of him to acquire an accurate and clear recognition of the nature of the several relations which have hitherto been engaging our attention with regard to those organized residual products which give development to what are termed the phenomena of animal life.

I am here induced to solicit thus much of the reader, from an apprehension that unless he have a clear and distinct comprehension of the nature of the relations which

have already been investigated with regard to those residual products, he might not perhaps so clearly and distinctly comprehend the nature of the relations (with regard to those products) which remain for us *still* to investigate, and consequently might not perhaps with the same facility be enabled clearly and distinctly to recognize the full force of the observations I am now desirous of submitting to his judgment. To obviate such embarrassment with regard to any of my readers, I shall then, before entering in detail upon the question more directly before us, devote the present communication to an attempt to place as concisely and at the same time as clearly as may be before their view—1st, *the relations* (with regard to the *ultimate results* of the regenerative process) to which I have *already* endeavoured to direct their attention; and 2nd, *those relations* (with regard to such products) to which I am *now* desirous of directing that attention. Hitherto we have been chiefly occupied with inquiries into the nature of the two following relations—namely, we have been investigating the nature of the relation in which the various *organizing agents* employed in the generation of those final results—that is, those *agents* concerned in raising *mineral matter*, by progressively ascending steps, to the condition of the ultimate results of the regenerative process, to the condition of those *organized structures* which give development to the phenomena of animal life; hitherto, I say, we have been chiefly inquiring into—1st, the nature of the relation in which the several *organizing agents* so employed stand towards *each other*; and 2nd, the nature of the relation in which those several *organizing agents* stand towards the *organized residual products* which it was the specific function of those agents respectively to generate. In a word, we have hitherto been investigating the nature of the relation which subsists—1st, between *organizing agent* and *organizing agent*—that is, between one *organizing agent* and another; and 2nd, between an *organizing agent* and an *organized residual product*. Thus much, I say, I have *hitherto* made an attempt to investigate, but *as yet* we have made no inquiries as to the relation which subsists between *residual product* and *residual product*—that is, between one *organized residual product* and another. *As yet*, I say, we have entered upon no investigation whatsoever as to the relation which subsists between one of the *final results* of the regenerative process and another of those *final results*; between one of those organized structures designed to develop *phenomena of animal life*, and another of the structures designed to develop *such phenomena*. In a word, we have as yet made no inquiry whatsoever as to the nature of the two following relations—namely, as to the relation in which the various final results of the regenerative process stand—1st, with regard to *external creation*; and 2nd, with regard to *each other*. We have as yet, I say, learned nothing as to—1st, *how* nervous tissue, vascular structure, muscular fibre, and cerebral matter *collectively*, are related to surrounding creation, with which they are obviously in *some way* related; or secondly, *how* those structures, *separately and individually*, are respectively related to *each other*. We consequently have still to inquire—1st, *how* the *united results* of the regenerative process are connected with the world that surrounds them; and 2nd, *how* the *individual results* of that process are connected the one with the other. Such, I say, are the *general* questions which, as it appears to me, still remain for investigation with regard to the *final or ultimate results* of the regenerative process. In order to obviate any obscurity or ambiguity my observations in connexion with the investigation of these questions might otherwise possibly present to some of my readers, I shall, as I have observed, devote the present communication to an attempt to place, concisely and briefly, before the observation of such—1st, *the facts* which I have *already* attempted to establish with regard to the final results of the regenerative process; and 2nd, *those facts* (with regard to such products) which, as I regard it, *still remain* to be ascertained.

The facts which I have *already* attempted to establish with regard to those organized structures, which I have

termed “*the final or ultimate results of the regenerative process*,” I shall for perspicuity reconsider under the two following divisions—namely, 1st, those facts which have a relation to the *forming or constructing* (that is, in other words, to the *generation*) of those structures; and 2nd, those facts which have a relation to their *function*. First, then, as to the facts we have *as yet* learned with regard to the *generation* of those products. We have already seen, in the first place, or in relation to the forming or constructing of the animal tissues—that is, in other words, in relation to the *generation* of those tissues; we have, I say, already seen, in the first place, *how* those residual products or *organized structures* have obtained their *organic existence*, although composed of inorganic or mineral elements—that is, although composed or constructed of identically one and the same species of *material constituents* as enter into the composition or construction of *unorganized structures*. In other words, we have seen *by what process* nervous tissue, vascular structure, muscular fibre, and cerebral matter are generated or brought into being from an *unorganized or mineral world*. We have seen that process to be what I have termed the *process of generation*. We have further seen (that is, in addition to the recognition of the process), we have, I say, further seen (and my readers will have the goodness to mark this distinctly), we have further seen the *agency or instrumentality* whereby the generation or construction of those organized structures has been *caused or accomplished*—namely, by what I have termed an *organizing agent*. Thus much, I say, we have already seen, in the first place, or in relation to the *generation or construction* of those structures. Let us then proceed to the second inquiry, and ascertain what we have *as yet* learned with regard to those structures when the process of constructing or of generating them *has been accomplished*; what we have *as yet* learned with regard to those *organized tissues* in relation to their *final destination*; in relation to the *end or design* with which their generation or organization has taken place. Let us, in a word, proceed, in the second place, to inquire: What we have *as yet* learned with regard to the ultimate or final results of the regenerative process in relation to the *functions* those products are called upon to fulfil. Having clearly and distinctly before us the facts which have *as yet* been ascertained with regard to those functions, we shall have the less difficulty in recognizing the nature of the facts which (with regard to those functions) remain for us *still* to investigate.

We have, then, *already* seen, in the second place, or in relation to the *function* of the organized residual products before us—that is, in relation to the *function* of those organized structures which develop the phenomena of animal life; we have, I say, *already* seen *how or in what manner* those residual products or organized structures develop their physiological functions. In other words, we have *already* seen by what *process* (that is, by what *alteration or change* in the position or arrangement of their own component constituents) those *organized structures* respectively give development to phenomena of animal life. We have seen that process to be a *parting* (to an extent *proportional* to that in which the *function* of the organized structure *has been discharged*), we have seen it, I say, to be a *parting* with the *cause* (whatever it be) of the *organized condition* of that structure; we have seen that *change or alteration* to be a *resignation* (to an extent *proportional* to that in which the *function* of the organized structure *has been discharged*), we have seen it, I say, to be a *resignation* of that (whatever that be) which had hitherto retained the components of that structure in what is termed an *organized condition*. In a word, we have seen that process to be what I have termed the *process of disorganization or degeneration*. Thus much, I say, we have *already* seen, in the second place, or with regard to the *function* of the organized structures which develop the phenomena of animal life; but mark this distinctly, we have *not as yet* seen, and have consequently *still* to investigate, the *cause* of the alteration or change just referred to. We have not as yet seen, and

have consequently still to inquire for the *means whereby* that *parting* (with the *cause* of the organized condition) *has been effected or brought about*; the *means whereby* that *resignation* (of that, whatever it be, which retained the components of that structure in the organized condition) *has been caused or accomplished*. We have not as yet learned, and have consequently still to inquire *how* those organized structures have been *caused* to assume that condition *which eventuates in their reconversion into inorganic or mineral matter*. In a word, we have not as yet learned, and have consequently still to investigate, the *agency, instrumentality, or means* whereby the disorganization or degeneration of those organized structures *is accomplished*. Upon this topic, I say, we have as yet made *no inquiries whatsoever*. We have learned how those organized structures develop their physiological functions—namely, by *assuming* or by *being placed* in that condition which *adapts* them for being eventually reconverted into *inorganic or mineral matter*. In a word, we have seen that those structures develop their functions by *undergoing* what I have termed the *process of disorganization or degeneration*; but we have not as yet learned, and have consequently still to inquire, *how* that process of disorganization *has been caused*; we have not as yet seen, and have consequently still to inquire, for the *agency* by whose *instrumentality* or *means* the degeneration of those organized residual products *is brought about*. Let me be distinctly understood. In one of my former communications, I directed the reader's attention to the fact, that there are but four circumstances or conditions under which it is possible to contemplate what we term *ponderable or physical matter* in its relation to what is termed organization and life—namely, that such matter must be contemplated while in one of the four following conditions—viz., either, 1st, while *devoid* of organization and life—that is, while in the condition of *dead, unorganized, or mineral matter*; 2nd, while in the act of being *elevated* in the scale of organization; 3rd, as matter possessed of what I have termed *quiescent vitality*; 4th, and finally, while in the act of being *degraded or of descending* in the scale of organization. In one or other of these four conditions or states must any *given specimen* or *special example* of what are termed ponderable or material constituents be contemplated in its relation to what is termed organization and life. I have selected *muscular fibre* as that given specimen or special example of material constituents for the purpose of watching the ponderable components of that muscular fibre while in *each* of the four foregoing conditions. *As yet* I have contemplated those material constituents, or ponderable components, while in the *first, second, and fourth* of the four conditions referred to—that is, while *unorganized*, or while existing as *mineral matter*; while *ascending* in the scale of organization; and finally, while *descending* in the organized scale.

The circumstances to which, in relation to those components, as contemplated in the three conditions referred to, I am now desirous of recalling the reader's attention, are the following two—namely, 1st, we have seen *how*—that is, by *what agency or means*, the material components of muscular fibre have been *raised* to the *third* of the four foregoing conditions. In other words, we have seen the *instrumentality whereby* mineral matter has been elevated to the condition of *muscular fibre possessed of quiescent vitality*; and 2nd, we have seen those material components *while* in the *fourth* of the conditions referred to. In other words, we have seen the ponderable constituents, of which muscular fibre is formed, *while* those constituents were *in the act of being degraded in the scale of organization*. We have, I say, seen those constituents *while* in that fourth condition; but mark this distinctly, we have *not* seen *how*—that is, by *what agency or means*, the assumption of that fourth condition *has been caused*. We have not as yet learned, and have consequently still to inquire, for the *instrumentality whereby* the components of muscular fibre have been *caused* to depart from or leave their *quiescent* condition, and to assume the condition of muscular fibre

*in the act of being degraded in the scale of organization*.\* Upon this, I say, we have as yet made no inquiries whatsoever. Such being the case, I am now desirous of contemplating the components of muscular fibre while in the *third* of the four foregoing conditions—that is, while those components exist in the state of *muscular fibre possessed of quiescent vitality*, and that for the following purpose—namely, in order to obtain a reply to this question—viz., *what is the agency or means* whereby the components of muscular fibre *are caused* to leave the condition of *quiescent vitality*, and to descend in the scale of organization? What is the *instrumentality* whereby the constituents of that *organized* residual product *are caused* again to approach the *unorganized or mineral world*? What, in a word, is the *agency* whereby the *disorganization* of the final results of the regenerative process *is accomplished or brought about* when the process of *organizing or of constructing* those products has been *completed*? I trust I have expressed myself clearly. Lest, however, it should be otherwise, I shall endeavour to be more explicit.

My readers are aware of what, in *physical science*, is meant by the terms "*vis inertia*" of matter. There is a *physiological* as well as a *physical inertia*, and I would urge upon the reader, before proceeding further with this subject—first, to *convince himself of the soundness*; and secondly, to *reflect upon the physiological bearing* of the following statement—the truth of which admits of no question—namely, the various organized residual products which respectively develop what are termed "phenomena of animal life," such as nervous tissue, vascular structure, muscular fibre, and cerebral matter; these several structures, I say, when the business of *forming or of constructing* them has been *accomplished*—that is, in other words, when the process of their generation has been completed and has ceased; then, I say, these structures respectively exist in the condition which I have termed that of matter *possessed of quiescent vitality*, and in that condition it is *absolutely essential* (in accordance with the existing state of things) that such structures must *ever continue to exist* until they have been operated upon by *some cause* which is competent to destroy or disturb that condition. In that quiescent, inactive, or dormant condition, I repeat it, *all* organized structures (be the nature or function of such structures what it may) *must for ever remain*, during the duration of time, until they have been acted upon by *some agency or means* which can *cause* them to *leave* that condition; until they have been operated upon by *some instrumentality* which can arouse or disturb their quiescent vitality, and *cause* them to *descend in the scale of organization*. In a word, until they have been acted upon, if I might so term it, by *some force*, which can overcome, if such terms be permitted, the *physiological vis inertia* of those structures.

*What is that cause for each of the four orders or classes of organized structure before us? What is the force* (if such term be allowed) provided by Nature for overcoming the *inertia* of those organized structures *respectively*? What, in a word, is the *agency, instrumentality, or means*, which Nature has supplied *whereby* nervous tissue, vascular structure, muscular fibre, and cerebral matter shall be *caused* in the *normal or natural manner* (that is, in conformance with Nature's design), what, I say, is the *agency, instrumentality, or means* provided by Nature whereby those structures respectively shall be *caused* to leave their

\* The reader, I trust, understands me distinctly: what I desire to convey is, in other words, this—namely, we can see the *some* material constituents at different periods while existing in the two following very different conditions—viz., 1st, *while* those constituents constitute one of the component parts of *man*—that is, in other words, *while they exist in the highly organized condition* to which we give the name *muscular fibre*; and 2nd, *while* those constituents constitute one of the component parts of *urine*—that is, in other words, *while they exist in the scarcely organized condition* of the components of that effete compound. The question before us is this—namely, *how* has the *change* in these constituents been effected?

condition of *quiescent vitality* and to assume the condition of matter in the act of being degraded in the scale of organization? What, I repeat, has been the *special provision* made specifically for this purpose by Nature for each of those four orders of structure individually? This is, as I conceive, an important physiological inquiry, and merits, as I regard it, the reader's attention.

There are two facts in relation to the question before us (that is, in relation to the *special provision* which Nature has made for causing or bringing about the disorganization or de-generation of the four orders or classes of organized structure referred to), there are, I say, two facts in relation to this question which will at once be admitted by all—namely, 1st, that the organized structures referred to do undergo the process of disorganization or degeneration during or subsequently to the development of their physiological function; such structures being eventually reconverted (from the condition of organized structures) into inorganic or mineral matter; and 2nd, that the oxygen of the atmosphere combines with certain of the components of those organized structures during or subsequently to (but mark it distinctly, *not antecedently* to); and 2ndly, I say, that oxygen of the atmosphere combines with certain of the components of those organized structures during or subsequently to the discharge of their physiological function—that is, during or subsequently to the development of the phenomena of animal life; which combination of oxygen with those components acts as a cause of the disorganization or de-generation of those organized residual products, and of their eventual reversion into inorganic or mineral matter. In the oxygen of the atmosphere, then, we recognize a portion of the special provision which Nature has made for causing or bringing about the disorganization or de-generation of the organized structures referred to, and their ultimate reduction to the unorganized state. That such is a fact, there is no physiologist will question.\* In a word, in the oxygen of the atmosphere we recognize the incidental stimulus, in the absence of which it is impossible (consistently with the arrangements which Nature has made) that those organized structures could (in a normal or natural manner) discharge their required physiological functions. The presence and operation of an incidental stimulus, such as oxygen, is, I say, requisite to enable those structures (in a normal or natural manner) to discharge their respective physiological functions; but such incidental stimulus, though requisite, would, alone (that is, in the absence of some other operating cause), such incidental stimulus, I say, would, if alone, be utterly incompetent to accomplish that end.

I have just employed (in relation to oxygen gas) the expression "a portion" of the special provision which Nature has made for causing or bringing about that effect, and that for the following reason—namely, to me it appears to be obvious that some other element, or operating cause, must, of necessity, have been also in operation before that result could, in a normal or natural manner (that is, in conformance with existing arrangements), before, I say,

\* Should there be any of my readers (which is scarcely likely to be the case) who may feel any doubt or uncertainty as to the correctness of either of the two statements contained in the above paragraph, I would beg of them to ask themselves the two following questions, and to reflect for a moment as to what must be the rational reply—namely, from whence is derived the urea, the lithic acid, the phosphates, &c., of our urine, as also the carbon of expiration? Where do these several substances come from? Why do they exist? and from what source have they been formed? And 2nd, why is the amount of the several components respectively (contained in that urine, expired air, cutaneous expiration, &c.), why, I say, is the amount of these several components strictly proportional (in the normal state of things) to the degree of activity or energy with which the organized structures referred to have respectively discharged their physiological functions? A very little reflection upon each of these questions will, I feel assured, enable any of my readers to convince himself that the two statements contained in the above paragraph are facts.

that result could by possibility be accomplished. For there is a third fact in relation to the question before us, to which I would now desire to solicit the reader's attention; and I would urge upon him seriously to reflect upon the subject until he be enabled to determine to his complete satisfaction whether the inference which, as I regard it, is to be drawn from that fact, be a legitimate deduction or be unsound. The fact I refer to is this—namely, that none of the organized structures at present before us (that is, none of the residual products which develop the phenomena of animal life), that none, I say, of those structures discharge their physiological functions uniformly and uninterruptedly with one and the same degree of activity or energy. In other words, that neither nervous tissue, vascular structure, muscular fibre, nor cerebral matter; that no one of these structures, I say, discharges its specific physiological function at all times with one unvarying and constant degree of intensity. On the contrary, it must be manifestly obvious to all, that each of those structures discharges its physiological function at various times with a variable degree of activity, intensity, or energy. That such is a fact, is too obvious to require further observation. And what do we collect from the recognition of this fact? what inference of importance is to be deduced therefrom? We may, as I conceive, collect this, as I regard it, important physiological deduction—namely, that the discharge of the function of each of those structures, both as regards the time and the intensity of that discharge, must have been placed by Nature under some regulation or control, and cannot have been abandoned to mere hazard or chance. We collect, I say, as I regard it, this important physiological fact—namely, that there must be something (whatever it be) which regulates, arranges, establishes, or controls each of the two following points—namely, 1st, the period or time at which; and 2nd, the degree of activity or intensity with which the oxygen of the atmosphere shall act upon the components of the organized structures referred to. There must, I say, be something, be that something what it may, in the absence of the operation of which, it is absolutely impossible (consistently with existing arrangements) that the oxygen of the atmosphere could (in a normal or natural manner) produce its disorganizing effects upon those organized structures. In a word, there must be something (specially endowed with such function by Nature), in the absence of the operation of which, the component constituents of those organized structures would not be so circumstanced, placed, or conditioned as to admit of oxygen producing thereon its disorganizing effects; would not be so circumstanced, placed, or conditioned as to admit of oxygen eventually reconvert those organized structures into unorganized matter. There must be something in the absence of which those organized structures, though exposed to the influence of oxygen gas, would still retain their condition as organized structures. In fine, there must be something (whatever it be) in the absence of which their incidental stimulus is incompetent to produce its required effects upon those organized structures.

Let me be distinctly understood. If it be true, in the first place, that the discharge of the functions of each of those structures is dependent upon, or accompanied with, some such alteration or change (whatever that change or alteration may be) in the arrangement, constitution, or organization of the component constituents of which that structure is formed; that the discharge of the function, I say, of that structure is dependent upon some such change in its own constitution as prepares or adapts its components for entering into combination with oxygen gas; or in other words, some such modification or alteration in its own organization as admits of those components entering into such combination (for observe, before the discharge of the function of that structure had commenced, its components did not enter, or evince any disposition to enter, into combination with oxygen gas); if, I say, it be true, that the discharge of the function of each of those structures is dependent upon such modifica-

tion in its own constitution *as admits* of its component constituents entering into combination with oxygen gas, whereby that *organized* structure eventually becomes reduced to the condition of *unorganized* or mineral matter. In a word, if it be true, in the first place, that *the discharge of the function* of each of those structures is *dependent upon* what I have termed *the process of disorganization or degeneration* (and there are perhaps none of my readers will question that fact); if it be further true, in the second place, that some such arrangement *must* (in accordance with the existing state of things) have been adopted by Nature *as to admit* of the function of each of those structures *being discharged* (as circumstances may demand) *at various times with various degrees of activity or energy* (and it is impossible, as I regard it, that any one could question this fact); and finally, if, in the third place, it be also admitted that *the ability or adaptation* of the components of each of those structures to enter into combination with oxygen gas, *is strictly proportional* to the degree of activity or energy with which that organized structure has discharged its physiological function (and a comparison of the degree of activity or energy with which the function of these several organized structures has been discharged—a comparison, I say, of such activity with the results of an analysis of the urine, expired air, cutaneous transudation, &c., during and subsequently to the discharge of that function, will banish all doubts as to this statement being fact, should such doubt exist in the mind of any of my readers). If, I say, it be true that the three foregoing statements are *facts* (and to me it does not appear that they admit of being questioned), then, as I regard it, the following deduction results as a *necessary consequence*, as an *indisputable* (as I conceive) or *unquestionable inference*—namely, that *some provision* (whatever it be) *must have been made* by Nature whereby *an adaptation or ability*, on the part of the components of the organized structures which develop the phenomena of animal life, *to enter into combination* with oxygen gas, *shall be strictly proportional* to the *constantly varying* degree of activity or energy with which it is required that those structures should at various times discharge their physiological functions. In other words, that *some plan or arrangement* (whatever it be) *must have been adopted* by Nature whereby *the union* of oxygen gas *with the components* of those structures may be *regulated*, both as regards *intensity* and *time*, in such a manner *as to admit* of the function of each of those structures being discharged *at various times with various degrees of activity or energy*. I trust I convey myself clearly. What I desire to express is, in other words, this—namely, 1st, *the discharge of the function* of the various structures referred to *has* (as regards *time* and *activity*) *been made proportional* to the union of oxygen gas with certain of the components of those structures; 2nd, *the discharge of the function* of the various structures referred to *has not* (as regards *time* and *activity*) *been abandoned* by Nature *to mere hazard or chance*, but has, on the contrary, been placed under the control or subjection of *something* (whatever that something may be) whereby *that function may be discharged at various times with various degrees of activity*. Consequently, *the union of oxygen gas* with the components of the various structures referred to *cannot* (as regards *time* and *activity*) *have been abandoned* by Nature *to mere hazard or chance*; but, on the contrary, *must have been placed* under the control or subjection of *something* (whatever that something may be) whereby *the union of oxygen gas* with the components of those structures *may take place at various times with various degrees of activity*.

In other words, *something* must have been specially provided by Nature whereby *the union of oxygen gas* with the *component constituents* of the organized structures referred to may be regulated, may be timed, may be proportioned; in a word, *may be controlled*. *What* is that *something* for each of the organized structures before us—namely, for nervous tissue, for vascular structure, for

muscular fibre, and for cerebral matter? *what*, I say, is the *special provision* which Nature has made for supplying that *something* for each of the *organized residual products* which develop the phenomena of animal life? Such is the question to which I would desire to direct the reader's attention\*—namely, in other words, *what is it* which

\* Should there be any of my readers to whom *the necessity* for the provision above referred to may not be at first sight apparent, I would beg of him to ask himself the following question, and to reflect for a moment upon what must be the rational reply—namely, *why is it* that a grain of corn may remain for an indefinite number of years in our barns, where it is *freely exposed to the influence of oxygen gas*, without evincing the smallest tendency whatever *to change its condition*—without evincing the smallest tendency whatever *to vary the relative arrangement of its component constituents*; in a word, *without any of those component constituents manifesting the slightest disposition to enter into combination with oxygen gas, or to be altered in any way by that agent*? *Why*, I say, is this so, when we find that so soon as that grain of corn has been thrown upon the earth, that then (if exposed to the influence of oxygen gas) it does at once evince a tendency *to change its condition*—that then it does at once evince a tendency *to vary the relative arrangement of its component constituents*—that then, in a word, those component constituents *do manifest* a disposition *to enter into combination with oxygen gas, or to be altered in some way by that agent*? *Why*, I repeat it, has this been the case? The answer to that question must, as to me it appears, be this—namely, the agency or instrumentality (whatever it be) which has been provided by Nature for the purpose of causing the required change in the relative arrangement of the components of that grain of corn; or in other words, which has been endowed with the faculty of *placing* those components in such a position (in which position observe they had not previously been), in such a position, I say, as to admit of their entering into combination with, or be in some way affected by, oxygen gas; the agency or instrumentality, I say, so endowed or provided for this purpose by Nature, *was not in operation* (or at least was not so in operation as to produce that effect) until that grain of corn had been thrown upon the earth. In a word, we may, as I regard it, from the contemplation of that grain of corn in the two foregoing positions, collect the two following facts—namely, 1st, that the operation of some specific cause (whatever it be) is required to effect or bring about that action or change (whatever it be) in that grain of corn whereby its components become adapted for being affected by the oxygen of the atmosphere, *whatever be the effects* produced by that oxygen in the components of that grain of corn; and 2nd, that *this specific cause* (whatever it be) exists (or else is called into action by something which exists) in the earth upon which that grain of corn has been thrown.

We have already, in one of my early communications, investigated the question as to the causes which, and which alone (in a normal or natural manner), can, by possibility, effect or bring about the changes observed to take place in the relative arrangement of the components of that grain of corn. In other words, we have inquired into the requisites which Nature has made it essential should be fulfilled before the functions of any "vegetation" in existence can be discharged. Those requisites we have seen to be twofold—namely, 1st, the presence of what I have ventured to term an "incidental stimulus;" that is, the presence of some chemical agent (such as oxygen gas) which is capable of producing some chemical effect upon, or of entering into chemical combination with, some of the components of that "vegetation" or organizing agent. In a word, the presence of some agent which can augment the chemical force already existing in the components of that "vegetation" or organizing agent, so as to increase the tendency they have to enter into chemical combination; and 2nd, the presence of what I have ventured to term a specific stimulus, in the absence of which specific stimulus (whatever it be) it is absolutely impossible that that "vegetation" or organizing agent could in a normal or natural manner (that is, in accordance with the design Nature had in view in creating that agent), it is, I say, absolutely impossible that that "vegetation" could in a normal manner discharge its required physiological function. In the absence of which specific stimulus (whatever it be) it is absolutely impossible that the incidental stimulus, or oxygen gas, could in a normal manner (or in accordance with Nature's design) enter into chemical combination with (or produce other chemical effect upon) the components of that "vege-

(conjointly with, or in addition to, their *incidental stimulus* or oxygen) acts as the *efficient cause* whereby the disorganization or degeneration of those several *organized structures* is accomplished?

The reader, on entering upon the consideration of this subject, will please to bear distinctly in mind that the question at present before us is this—namely, what is that *efficient cause* which (conjointly with, or in addition to, oxygen gas) has been provided for each of the *organized residual products* in question? I say, *organized residual products*, in contradistinction to *organizing agents*; for we have *already* investigated the same inquiry with regard to organizing agents. I shall, for perspicuity and clearness, briefly recal to the reader's attention some of the results of that investigation with regard to *organizing agents*. In one of my earlier communications, I endeavoured to direct the reader's attention to the three following facts—namely, 1st, that the humblest or lowliest species of *organizing agent* (that is, in other words, the simplest conceivable *vegetation*) *does not commence* the discharge of its specific physiological function (although *freely exposed* to the influence of oxygen gas), *does not begin* to develop the phenomena of *organic life* (although surrounded by an atmosphere of oxygen) *until* it has, in the first place, been presented (in the form of *unorganized or mineral matter*) with materials which stand to that *organizing agent* in the relation of what is popularly

termed "its nutriment." *Until*, I say, that *organizing agent* has been presented with such materials, it might (though *freely exposed to the influence of oxygen gas*) remain *for ever* in the condition of an *organizing agent* possessed of *quiescent vitality*. When, however, that *organizing agent*, thus exposed to the influence of its *incidental stimulus* or oxygen, has been presented with such materials (in conjunction with certain other requirements, such as temperature and moisture), *then*, and *not till* then, is the *quiescent condition* of that *organizing agent* *disturbed*; then, and not till then, does that *organizing agent* *commence* the discharge of its specific physiological function of developing the phenomena of *organic life*; *then*, in a word, and *not till* then, does that *organizing agent* begin to *confer* or to *impart* organization. To such fact, I say, I have already directed the reader's attention in the first place; 2ndly, I have further endeavoured to point out to the reader that if by *any abnormal process* (viz., *high temperature*, for example; such, for instance, as throwing the seed of a vegetable into the fire), that if, I say, by the operation of any *abnormal cause*, the oxygen of the atmosphere be *forced* to act upon the components of that *organizing agent*, and to reduce them to the condition of *unorganized matter*; that *then*, I say, that *organizing agent* (though *caused* to undergo the process of disorganization or degeneration) *does not* (in the absence of what *normally* acts as that cause), *does not*, I say, undergo that process in a *normal or natural manner*; that *then* that *organizing agent* (though *caused* to undergo the process of disorganization or degeneration) *does not* (in the absence of what *normally* acts as that cause), that *then*, I say, that *organizing agent* *does not* discharge its *specific physiological function*. In a word, that when the *disorganization or degeneration* of an *organizing agent* is *caused exclusively and alone* by an *augmentation of the chemical or physical forces* which already exist in the components of that *organizing agent*, that *then* that *organizing agent*, although reduced to the condition of *unorganized matter*, *does not* (while in the act of undergoing the process of that reduction) *discharge* its specific physiological function; *does not*, while in the act of undergoing the process of degeneration, *develop* the phenomena of *organic life*; in a word, *does not*, while in the act of undergoing the process of disorganization, *confer or impart organization*. Hence we collect the necessity for the presence and operation of some *specific cause* of that disorganization to enable that *organizing agent* (while undergoing such disorganization) to *discharge its specific physiological function*. To such fact, I say, I have already directed the reader's attention in the second place. 3rdly, I have further, in the third place, endeavoured to make it apparent to the reader that the *same facts* are equally true with regard to *all* *organizing agents* in existence, from the lowliest or most humble to the most elevated or lofty, *all without exception* require the presence and operation of materials in the form of what is popularly termed "*their nutriment*," before in a *normal or natural manner* (though *freely exposed to influence of oxygen gas*) they can undergo the process of disorganization or degeneration. In a word, *all organizing agents*, without a solitary exception, require the presence and operation of certain *specific or special materials* which stand to such *organizing agents* in the relation of what is popularly termed "*their nutriment*," through the agency or operation of which *specific or special materials* (conjointly or in conjunction with an *incidental stimulus*, such as oxygen gas) those *organizing agents* may be *aroused* from their condition of *quiescent vitality* and *caused* to discharge their specific physiological function.

tion" or *organizing agent*; and thus *increase* the tendency those components have to enter into *chemical combination*. The grain of corn just referred to, may, as we have seen, remain for an indefinite number of years in our barns without evincing the smallest tendency to undergo *any change whatever*; without all or any of its components manifesting the slightest disposition to enter into *chemical combination* with, or to be in *any other way affected* by oxygen gas, although during that period *freely exposed* to the influence of that *chemical agent*. Why is this so? Simply, as it appears to me, for this reason—namely, *because the specific stimulus* of that *organizing agent* was *absent*. The *specific stimulus* (namely, that, whatever it be, which *so acts* upon the components of that *organizing agent* as to place those components in such a position as *adapts them* for being *affected* by oxygen gas, and for entering eventually into combination both with that gas and with each other), the *specific stimulus*, I say, of that *organizing agent* (whatever it be) we have already seen to exist in the earth. When, then, that *organizing agent* has been thrown upon the earth, *then*, and *not till* then, can it (in accordance with Nature's design) discharge its specific physiological function of—developing the phenomena of *organic life*.

Such, I say, as it appears to me, has been Nature's arrangement with regard to what I have termed *organizing agents*. The same, identically the same, appears to me to have been also her arrangement with regard to what I have termed *organized residual products*. Identically the same species of requisites must, I say, as it appears to me, of necessity, be in operation, in order to cause one of the final results of the regenerative process to manifest its specific physiological function of developing a phenomenon of *animal life*. They, too, one and all, require the presence and operation of an *incidental* and of a *specific stimulus* to admit of their discharging their respective physiological function in a *normal or natural manner*. In a word, they require—1st, the presence and operation of oxygen, whereby the *chemical force* (already existing between their components) may become *so augmented* as eventually to cause a union of those components with that oxygen and with each other; and they require, 2nd, the presence and operation of *something* (be it what it may), the presence and operation, I repeat it, of *something* which can place those components (which *previously* to the operation of that something *had not been so placed*), the presence and operation, I say, of *something* which can place those components in such a position as to admit of their being influenced by the operation of oxygen gas, and of eventually entering into *chemical combination* with that gas and with each other.

What is that *something* for each of the *residual products* before us? Such is the question to which I am desirous of directing the reader's attention, and it is to that *something* (whatever it be) to which I would apply the terms *specific stimulus* of such *residual product*.

To those materials which stand to *organizing agents* in the relation of what is popularly termed "*their nutriment*," I have ventured to apply the following terms—namely, the *specific stimulus* of those *organizing agents*; I have done so for the two following reasons—namely, 1st, from the fact that (while the term "*nutrition*" appears to me to express but little which can convey any *very definite*

ideas to the mind) *the specific physiological function* of those materials is to *arouse or stimulate* the organizing agents (upon which they have been adapted by Nature for acting) to the *discharge of their specific physiological function*; and 2nd, from the fact that *that* (whatever it be) which discharges an *analogous* function with regard to *organized residual products*, does not stand in the relation of what is termed "nutriment" to those *residual products*. What is *that* which discharges an *analogous* function with regard to *organized residual products*? What is *that* whose *specific physiological function* is to *arouse or stimulate* to the discharge of its *specific physiological function* an *organized residual product*? Such is the question at present before us.

Thus, then, the question which I am at present desirous of attempting to investigate, may for perspicuity be expressed in these terms—namely, *What is the specific stimulus* (that is, the stimulus *specially* provided with that *specific design*) which has been furnished by Nature for the purpose of *calling or arousing* to the discharge of its *specific physiological function* each of those *organized residual products* respectively which are designed to develop what are termed "phenomena of animal life?" What, I say, is that *specific stimulus* which (in conjunction with their *incidental stimulus* or oxygen gas) can so act upon those *residual products* as (conjointly with that *incidental stimulus*) to be the *efficient means* whereby those *organized structures* become eventually reconverted into *unorganized matter*? What, I say, is the *specific stimulus* which has been *specially* provided for each of those *residual products individually*? Such is the question I am now desirous of attempting to investigate, and to the further consideration of which I shall proceed in my next communication.

(To be continued.)

#### HOSPITAL REPORTS.

##### NORWICH HOSPITAL.

#### *Popliteal Aneurism; Compression; Ligature of Artery; Amputation.*

B. W—, aged 34, admitted, November 15, 1851, under the care of Mr. Norgate. He is a strong, healthy-looking man, of a sanguineous temperament, is married, and his occupation is that of a farmer's labourer. His father died at the age of 33, from the rupture of a bloodvessel; his mother is alive, and in good health. He has had intermittent fever twice; seven years ago he had rheumatic fever, which lasted sixteen weeks; and he has been subject to occasional slight rheumatic attacks since; also occasional seizures of acute pain in the præcordial region, stopping his walk or work. He has never had venereal disease, nor has he been addicted to drinking.

About ten or eleven weeks before admission, having "felt a stiffness in the left ham" when he rose from the sitting posture, his attention was directed to that region, when he perceived a tumour of about the size of a nutmeg. He has no recollection of having strained himself; nor can he assign any cause for the appearance of this tumour. On the discovery of it, he applied poultices for two or three nights, and the pain was removed. In about three weeks, he again felt uneasiness in the tumour, which gradually increased in size up to the period of his admission. He did his work up to November 8th, on which day he was at plough.

*Condition on Admission.*—There is a pulsating tumour in the left popliteal space, fusiform in shape, and of about the size of a small hen's egg. On the application of the stethoscope, a distinct *bruit de soufflet* is heard, which, as well as the pulsation, ceases by making pressure on the femoral artery above. It can be entirely emptied of its contents, which are fluid. The fascia closing the popliteal space is tightened, but there is very little distension of the veins or infiltration of the limb; pulse about 80, regular. There is no evidence of cardiac disease, beyond a slight roughness in the sounds. The left lung is not in so satis-

factory a condition as one could wish; there is some dullness on percussion, with deficient expansion of the corresponding side of the chest. The patient was ordered small doses of digitalis and hyoscyamus, three times a day. Middle diet, without beer.

Mr. Norgate was desirous of attempting the cure of this case by compression, by means of the instruments used by the Irish surgeons, and had already ordered them to be made; but on the 20th of November the tumour had so increased in size, and with it the discomfort of the patient, that it became necessary to do something at once; and therefore, as a temporary means, it was resolved to make pressure with Signorini's tourniquet, which was applied over the femoral artery at the upper third of the thigh. November 25th. Pressure has been continued since the 20th, but has been unfortunately applied in an imperfect manner, for want of proper apparatus; meantime the tumour has enormously increased in size. Pressure is now being made by means of the thumb of another person applied over the artery at the groin, and great ease thus procured to the patient. 26th. Pressure, as employed yesterday, no longer affords relief to the patient; he is writhing with pain, which he describes as existing all over the knee, ham, and leg, accompanied by coldness of the foot. The aneurism has now all the appearance of having become diffuse; the entire ham is one pulsating mass; the tumour has extended up the inner aspect of the thigh, to the extent of two inches; with all this obstruction, there is still but very slight œdema of the leg. Ordered forty minims of Battley's solution, to be taken directly. Bleeding to fourteen ounces. To have ten minims of tincture of digitalis every six hours, and a brisk cathartic at night. All compression to be discontinued. 27th. Patient comparatively easy since the bleeding; the blood drawn is highly buffed and cupped. 29th. The remedies adopted having somewhat quieted the system, it was resolved to tie the femoral artery, which was accordingly done to day, at half past twelve, the patient having been previously put under the influence of chloroform. The vessel was secured just where it is crossed by the inner edge of the sartorius. Two p.m.: Pulse 85; begins to feel pain in the leg similar to that which he experienced prior to the operation; the pain is more severe in the calf. Half-past two p.m.: He now describes the pain as excruciating. Half a drachm of Battley's solution, to be taken directly. Three p.m.: Pain slightly diminished; foot quite warm, but he says he cannot feel it. 30th. A grain and a half of acetate of morphia has been given in three doses during the night; this morning he is much easier, and says he feels his toes. Pulse 140.

December 1st. Pulse 108. Circumference of ham very much diminished, considerable tension in the ham, with a brownish discoloration and much pain; there is also commencing lividity of the foot and loss of sensation as far as the ankle. Temperature of sole, 83 deg., that of ham, 90 deg. 2nd. Pulse 105. The patient is much easier; the lividity of the foot has increased and has extended somewhat beyond the ankle; there is less tenderness and tension in the ham; but the pain on pressure is now felt lower down in the middle of the leg. Temperature of the sole, 77 deg. 5th. There is now considerable lividity of the foot to two inches beyond the ankle, at which point there is an obscure line of demarcation; beyond this the temperature is good and the limb appears restored; the entire surface below this mark is discoloured, but in some places more than others, forming patches; œdema of foot. To have a mutton-chop, brandy, eggs, &c. 6th. Vesication has commenced on the inner side of the ankle. The entire limb to be placed on an elastic cushion filled with hot water. 7th. Discoloration having now commenced in the calf, a consultation was held, and the immediate removal of the limb unanimously recommended. Mr. Norgate accordingly amputated the thigh, about four inches above the knee. Nothing worthy of record occurred during the convalescence of the patient, who was discharged, January 24th, with the stump quite healed.

*Dissection of the Limb.* The aneurism, occupying the

whole popliteal space, was of a nearly globular form, five inches long by four inches broad, and was nearly uncovered in making the posterior flap, the artery being cut about an inch from its expansion into the tumour. The minute examination of the tumour disclosed that it had its origin on the anterior and outer side of the vessel, and that its walls had given way when it had attained the size of a large walnut: also that it had become partially diffused into the inner head of the gastrocnemius, the aponeurosis of which formed its boundary above, and the torn muscular substance below. All the articular and the sural arteries were obliterated by pressure, or had their origin from the sac itself; the popliteal vein and nerve lay in a groove of the tumour, and had been subject to great pressure, as was to a less degree the peroneal nerve. The muscles of the posterior aspect of the limb were much altered in colour, though not shrunk in bulk, being mottled with what appeared to be fat in the interstices of their largest fibres. Above and below the disease the vessels were in a healthy state, save only the usual obliteration the the commencing line of demarcation. The cure of the aneurism had begun, by the formation of a firmish clot with some fluid blood below. The posterior ligament of the knee-joint was not diseased, nor the synovial membrane.—*Lancet*.

The opponents of the treatment by pressure will doubtless enumerate this amongst the unsuccessful cases, but with no fair grounds; for pressure was evidently, if applied at all effectually, so managed as to forbid success. We are surprised to learn that the proper instruments were not to be found in the *armamentarium chirurgicum* of the Norwich Hospital, or that they were not at once procured from London, where, we presume, they can be had.

#### PATHOLOGY OF DIABETES.

WE reprint the following from the 2nd volume of the Transactions of the American Medical Association:—"For all practical purposes in the present state of our knowledge, we may, in the opinion of Dr. Todd, adopt with advantage the following view of the pathology of diabetes. 'That it is primarily a disease of the mucous membrane of the stomach, whereby an abnormal diastase is formed, which rapidly converts into sugar such aliments as admit of that conversion; the mucous membrane probably likewise secretes sugar; the sugar thus formed, passes into the blood, and is rapidly eliminated by the kidneys, causing, at the same time, the attraction to those organs of the elements of a large quantity of water.' Very much to the same point are some interesting remarks of Professor Flint, in the *Provincial Journal*, on the pathology and treatment of this affection. The presence of sugar in the blood and various secretions other than the urine, he remarks, renders it inappropriate longer to rank diabetes among renal diseases. It is a disease affecting the assimilatory process, in consequence of which, sugar ingested passes unchanged into the bloodvessels, and alimentary principles capable of being converted into sugar undergo that chemical change. The kidneys are involved only as one of the excretory outlets by which this useless saccharine material is eliminated from the system. The hyper-secretory action of the kidneys (which is probably due to the presence of sugar acting as an excitement), constitutes an important element of the disease. This will serve to explain, in part, the dryness of the surface, the costiveness, the thirst, &c. The loss of those alimentary principles which contain sugar, or are capable of conversion into sugar, for all purposes of healthy assimilation, will explain the debility, the wasting, and the great gravity of the disease. We have thus advanced a considerable way in our knowledge of this disease; but we are still at a distance from knowledge of the nature of the perversion which the processes of assimilation undergoes, and of the ulterior morbid condition upon which the perversion depends. In other words, its true pathology and etiology are still unknown. The knowledge, however,

which has been acquired, is not without its practical value. It prevents, in the first place, treatment based upon the idea of its being essentially a urinary disorder, and other false pathological views, and in this way saves the patient from measures which might prove not only useless, but injurious. This, although negative, is nevertheless not the least important of the advantages which attend an improved knowledge of diseases generally. . . . Our rational course, in the present state of knowledge, is to endeavour to restore the proper action of all the functions; and especially to modify and improve the processes of assimilation."

M. Mialhe believes that diabetes "depends upon a want of sufficient alkalinity in the fluids of the body; that the transformation of amyloid substances into sugar, is not peculiar to diabetic patients; it is not an accidental phenomenon, but a necessary part of the digestion and assimilation of food; that this is brought about by an animal diastase in the saliva, which he has discovered; that amyloid substances must in all animals, without exception, be converted into sugar under the influence of this diastase. *But what becomes of this sugar?* It must participate in nutrition, and, in order to do this, it undergoes certain transformations; for in the normal state, it is not detected in any of the secretions. Its passage through the kidneys is pathological, and depends upon a disturbance which has its origin in the want of alkalinity in the blood. The alkalies in the blood, M. Mialhe contends, are the principal agents in the digestion and assimilation of saccharine and amyloid substances. The saccharine principle must undergo farther transformations to be assimilable. In the healthy subject, the alkalinity of the blood is sufficient for this decomposition; but if this be deficient, the transformation fails to take place; the sugar becomes a foreign body, and is cast off, not only by the kidneys, but by all secreting surfaces, and we have diabetes. The cause of this affection may therefore be traced to a defective assimilation of the sugar, through a want of alkalinity in the animal economy. Human blood is naturally alkaline, but would eventually become acid, through the ingesta, but for the counterbalancing effects of especial secretions—the urine and the perspiration, which when normal, are always acid. The saliva and the tears are uniformly alkaline."—*London Journal of Medicine*.

#### CALOMEL IN LARGE DOSES AS A DIURETIC IN DROPSIES.

By W. H. MCKEE, M.D., of Raleigh, North Carolina.

IN the treatment of dropsies, calomel has been considered from its earliest introduction into use, as a valuable adjuvant in combination with other remedies, but in no single instance am I aware that it is mentioned by writers as acting as a diuretic when given alone either in small or large doses. Its use in large doses is no new practice, for it has been given freely in the treatment of fever and cholera, and for its hydragogue, cathartic, sialogogue and deobstruent properties, it is well known. In combination with squills, nitre, and sometimes digitalis, it is a very popular mode of administration, and one that generally fulfils the indication for which it is prescribed; but there are cases in which it fails as well as the rest of the class of diuretics, and the physician is thrown back on his own resources for something more active and reliable. When such is the case, calomel in doses from forty to a hundred grains repeated for two or three nights successively, will certainly fulfil the most sanguine hopes, by not only freely purging, but by producing copious diuresis, and at the same time sedation, followed by sleep such as cannot be had from opium nor its preparations, with safety. During its action, gin or whiskey toddy may be freely used, should there be much prostration; but this is seldom the case, the stimulus only aiding the diuretic action. I have seen persons who were unable to lie down, for a week at a time, longer than a few moments, sleep well after the action of the first dose.

The usual mode of administration is to give fifty grains of calomel for three successive nights, and should it fail to produce the desired effect, to wait for several days and

repeat the calomel in eighty or a hundred grain doses, but in no instance that has come under my observation have I ever known the fifty-grain doses fail; and in but one case have I ever given a hundred grains. This was followed by free and copious purging at first, and in a short time by diuresis. It is not often that the first dose will act as a diuretic, but after the administration of the second its effects will be produced; the third dose I have never known to fail. During its action, it will, in some instances, produce violent emesis, and sometimes act as an emeto-cathartic; but this only facilitates its action, and no serious consequence may be apprehended. While using these doses, vinegar should be freely applied to the mouth and throat, so as to prevent its specific effect, and cold drinks of all kinds prohibited. Calomel given in the above doses is no more liable to produce its constitutional effect than it is when given in smaller ones. I have known one grain to produce salivation without accomplishing any good, but evidently harm. When the indication requires it, it should be used freely. As with quinine, we may produce ringing in the ears, and many contend that when this is the case, the specific effect is produced, and all is accomplished that may be expected of it. But this is known to be false. In the treatment of fever it is continued until the fever is subdued, without any detriment to the patient. So it is with the calomel in large doses in the treatment of dropsies. By using the necessary precaution, you can succeed in introducing into the system such quantities as will fulfil the indication, with no more danger than there is in giving smaller ones. When salivation is produced, it is as manageable as under any other form, and yields as promptly to the usual remedies. I do not recommend its use in these doses in all cases of dropsies, for many of them are merely functional, and the sequelæ of some acute disease, and readily yield to milder remedies; but it is in those cases where there may be hepatic and splenic derangement, when the ordinary remedies fail, that calomel may be relied upon, not only for its cathartic properties, but mainly for its diuretic action. So prompt is it in producing this effect, that I have known it to succeed in expelling the fluid where there was organic disease of both the heart and lungs. If the constitution of the patient is very delicate, for instance a female, doses of thirty to forty grains will be large enough. I was called to see a lady aged about 50, who had been pronounced by her medical attendant to be in the last stage of hydrothorax; with cough; bloody expectoration; great dyspnoea; inability to lie down; general anasarca and distension of the abdomen; countenance anxious; tongue red, pointed, and dry. She had taken a great variety of remedies, and appeared to be hourly growing worse. I prescribed thirty grains of calomel to be aided by whiskey toddy, and to be repeated the second night. The first dose produced copious purging, the second acted as an emetic with moderate purging, but with profuse diuresis. On visiting her the third day after administering the first dose, she was so much relieved that she was enabled to lie down and sleep with comfort, and to get up and walk without assistance. Her cough and expectoration ceased, tongue became moist, and all difficulty of breathing disappeared. But it is just to remark that the specific effect of the calomel was freely developed, but yielded promptly to the ordinary mode of treatment. After this, she was treated with chalybeates and the preparations of quinine, and recovered her usual health within a few weeks.

The diet in all cases should be very abstemious. After the action of the calomel, it will be necessary to administer some remedies to prevent a re-accumulation of the fluid. I have found a solution of the muriated tincture of iron to answer the indication very well, but in some instances it will disagree with the stomach. When such is the case, the tartrate of iron and potassa suspended in wine—about an ounce to the quart, and a dessert-spoonful given three times a day—will suit the most delicate stomachs, as well as fulfil the indication desired. Should the bowels become constipated, and require an aperient or cathartic, cream of tartar and Epsom salts equally combined will answer the

purpose. But should the re-accumulation of water take place in spite of these means, it will become necessary to repeat the calomel, and follow it by the same treatment. In a number of instances I have found the following combination to answer the purpose when most remedies had disappointed me, especially when the calomel was contraindicated from constitutional causes. Take one pint of the tincture of *asclepias syriaca*, which is made by adding one ounce of the fresh root to one pint of whiskey; let it stand for fourteen days, and then add it to two pints of the strong decoction of *sarsaparilla*, with one drachm of powdered alum. Of this, give a tablespoonful three or four times a day. Should it not be active enough, or too active, it may be regulated according to the ability of the patient to bear it. It will keep the bowels gently moved two or three times a day, besides acting as a good diuretic and tonic, increasing the appetite and strength.

Too much attention cannot be paid to the manner of dressing as well as the diet. Flannel should always be worn next the skin, and exposure of all kind avoided, especially in damp and rainy weather; for after the fluid has been expelled from the system, the muscular and cellular tissue is so much relaxed, that if these precautions are not attended to, and aided by proper bandaging of the abdomen, the fluid will, as a matter of course, re-accumulate. By adhering to this, the tissues are aided as they gradually assume their natural healthy and tonic action, and are enabled to resist the morbid influence; for, in fact, this is the great difficulty in curing hydropic diseases.

In confirmation of my own experience in the diuretic action of calomel, the following extracts from the published proceedings of the Medical Society of the State of North Carolina, will give additional testimony to its efficacy:—

“A discussion arose as to the *modus operandi* of calomel, on an inquiry made by Dr. J. Williamson of Caswell, if calomel was in fact a stimulus, or what was the received opinion as to its action? and he referred to an instance where it had been administered in very large doses by a friend, with decided benefit, in dropsy, acting as a sedative and diuretic at the same time.

Dr. C. Johnson of Raleigh remarked, ‘that he had considerable experience in the exhibition of both drugs (calomel and quinine) in large doses, and could testify to their sedative value and influence when given in this manner. Calomel, he believed, in doses of 50, 100, or more grains, particularly in some cases of dropsies, depending upon enlargement of the liver and spleen, and obstruction of the portal circulation, was followed by the happiest results, producing copious and free discharges, sometimes very watery, but not always corresponding in quantity with the increase of the doses, which was, perhaps, generally true of increasing doses of calomel; and that in many instances, sometimes after the second dose, more generally after the third, when the doses have been given day after day, it acted powerfully as a diuretic. He had seen many cases of dropsy of this kind improve rapidly, and speedily recover under this treatment. He had never seen salivation produced in this manner, although the action of the calomel was decidedly *sedative*, inducing quiet and sleep, diminished frequency of the heart’s action, and an improved state of the secretions generally, with a moist tongue and skin, and all without much if any prostration.’”

I am aware that it is too often the case that a general conclusion is drawn from a mere isolated fact, but such is not the case in the present communication. I could give a number of cases to illustrate the above treatment, but deem it unnecessary, as the general principle is here laid down. The main object in directing the attention of the profession to this subject at all is, that they may see what is the experience of others, and to show that calomel possesses a property far more reliable than has generally been conceded to it as a diuretic, and surpasses all other remedies of that class in dropsical diseases. Should the experience of others, after having given it a fair trial, accord with my own, I shall feel that my humble labours have not been in vain.—*Phil. Med. Examiner.*

### POISONING BY CAMPHOR ADMINISTERED BY INJECTION.

M. ARAN communicated to the Medical Society of the Hospitals of Paris a case of poisoning by camphor, which deserves to be better known, as the dose in this case is that directed in the latest formularies.

The subject of this case was a young woman, aged 27, who presented various nervous symptoms, and to whom, after having in vain made use of a number of remedies, M. Aran wished to administer camphor. For this purpose he prescribed four grammes (about sixty-one grains) of camphor in an injection; but two minutes after the administration of the injection, the patient complained of a sensation of sinking, and a pain in the abdomen. She then was seized with violent convulsions, with loss of consciousness, frothing at the mouth, twisting of the limbs, drawing of the head back, cyanosis of the face, coldness of the extremities, feebleness of the pulse, extreme dyspnoea, &c. This attack lasted twelve or fifteen minutes. The patient recovered her consciousness after cold water had been thrown on her, but was constantly choking, and said she was about to die. A purgative injection evacuated what remained of the camphor enema in the intestine; stimulant frictions were applied to the limbs, and an infusion of black coffee was administered every minute. The symptoms persisting notwithstanding, M. Aran placed the patient on a girthweb bed; the body was covered with sinapisms, sprinkled with water of ammonia, and for twenty minutes a continual stream of cold water was let fall on the head: at the same time were administered, as we have said, some mouthfuls of black coffee. These affusions calmed the agitation and anxiety. The pulse rose sensibly; then the patient was removed to a very hot bed, the coffee was continued, and an infusion of it given by injection, and thus every danger was overcome. The next day there remained only great feebleness, and not the least remembrance of what had happened.

The result of the discussion which followed this communication, and in which MM. Brousseau, Bricheteau, and Gendrin took part, that the dose of four grammes directed by the formularies is too large. It is better to commence with a small quantity, and gradually increase it. As to the means to be used in a like case, amongst the most are cold affusions, continued with perseverance, which are in this case of as much service as in other cases of poisoning, particularly in poisoning by hydrocyanic acid.—*Jour. de Méd. et Chir.*

### SUDDEN LOSS OF SIGHT BY LIGHTNING.

M. HENROTAY, regimental surgeon at Namur, reports the following case of sudden loss of sight, in consequence of a flash of lightning, in a patient who wore a galvanic chain round his neck:—

A man, named Geeraets, aged 38, of broken-down constitution, and lymphatic temperament, was employed as magazine guard at Beverloo. Overcome with old rheumatisms, which had stiffened all his joints, for some months back he had worn a galvanic chain hanging on his chest till last summer, when he was suddenly attacked with dyspnoea as one of the parapets from which he was separated by a short space was struck with lightning. When recovered from his emotion, in a quarter of an hour, he was able to reach home. This event had left but a feeble impression on his mind, when, on the 1st of May, in this year (1851), as he was sitting in his room, reading a newspaper, the window being open, immediately after a flash of lightning, Geeraets is suddenly affected with vertigo, he reels, holds on by the furniture about him, and loses his sight completely. At this time, the galvanic chain which he still wore, was simply carried round his neck. I was called to see the patient, with M. Warlomont, in a short time after the accident.

Geeraets had a distracted appearance; the eyes open and immoveable; the pupils slightly more dilated than natural, and very little sensibility. He complained of headache and vertigo. We found the pulse soft, feeble, and impressible; a bruit de raie in the heart; he complained of some nausea, slight thirst, anorexia, and slight pain in the epigastrium on

pressure. The state of the pulse and constitution of the patient prohibited general bloodletting. We directed twenty-four leeches to be applied behind the ears in two relays, sinapisms to the lower extremities, and the patient was put on the lowest diet. At the end of the second day, these measures having caused no sensible amelioration, I ordered a large blister to the nape of the neck. From this moment there was a manifest improvement, so much so, that on the sixth day the sight was completely restored. It is unnecessary to add that Geeraets hastened to rid himself of his galvanic chain, and buried it several feet below the ground.

This case proves that the galvanic chains, the use of which has spread with such singular rapidity in our country for some time past, are not entirely without danger. Writing this at a distance from any library, it is impossible for me to discover if cases of a like nature are recorded in authors; and as a practitioner may be at a loss as to what treatment to make use of under like circumstances, I thought it best to mention the good effects which followed the application of a large blister to the back of the neck.—*Archives Belges de Méd. Militaire.*

### POOR-LAW INTELLIGENCE.

#### MEDICAL DISTRICTS—KILLARNEY UNION.

D. C. COLTSMAN, in the chair.

DR. PURCELL said the question of the medical districts was for a long time in abeyance, and he hoped the board would come to some decision. The Commissioners were of opinion that six divisions were absolutely necessary to carry out the intention of the legislature. In that opinion he (Dr. Purcell) concurred. However, to meet the board in every way they could, the Commissioners were now satisfied to have but five. He had taken pains to make out five divisions accordingly, in two different ways, the schedule and map of which he would lay before them. He did not think the intention of the legislature could be carried out with less. He therefore hoped the board would agree to five, or else have six. Dr. Purcell concluded by laying the schedule and map on the table.

The Chairman said it was right to inform Dr. Purcell that the board had frequently discussed this question, and had been in communication with the Commissioners on the subject for some time. On every occasion upon which the question was discussed, the great majority of the board were of opinion that four medical divisions, and no more, should be formed. He now begged leave to ask whether Dr. Purcell was authorized, on the part of the Commissioners, to make a compromise between four and six?

Dr. Purcell—Certainly. We will be too happy to have the guardians meet us half way.

Mr. James O'Connell said it appeared that the area of the union was 250,000 acres. Now, Mr. Chairman, continued Mr. O'Connell, your knowledge as well as mine will show that a large proportion of that is water. Our beautiful lakes and mountains form a large part of it, and are not inhabited at all. In a union in Galway, the area of which is considerably larger than ours, four medical districts were deemed sufficient. If the majority of this board could for a moment suppose that giving an additional physician could in any way serve to alleviate the distress of the people, there is not a single member of the board who would not cheerfully acquiesce. But the great majority of the board think that, however good the intention of the legislature may have been, a more useless law, as regards Ireland, never emanated from the British parliament. What will those medical men do? What relief will they give? None can be relieved except those stricken down by poverty, who are not themselves paying rates. Now, it is notorious that the great majority of that class are relieved in this house. The relieving officers are told that if those poor people are not able to attend here themselves to send them here; so that the number to be relieved will be comparatively small. Then as to the nature of the relief, Dr. Maybury or Dr. Murphy is called upon. He finds the pulse of the patient, say, up to 100 or 120. The patient cannot be removed from his wretched hovel, where food is as essential as medicine, but the doctor has only the power of administering medicine, but no more. The conviction on the mind of the board was, in point of fact, that this law is of use only to one body of respectable men

in the south of Ireland—in quartering a number of young men on the only property in the country—land. Though, no doubt, the friends of some of those young gentlemen were anxious that the number of medical districts should be increased, the majority of the board, feeling that there was no necessity for more than four at all events, placed on record the opinions which had just been read. It was from no unwillingness to tax themselves that they had adopted this course. If the Commissioners' *sic volo sic jubeo* is to be all in all in the matter—if they persevere in forming an unnecessary number of divisions, the fault is not ours, and the board should allow the Commissioners or their professional advisers to carry out the law, if they force such a measure on us. A gentleman of rank and high respectability in the neighbouring union of Tralee (Mr. Crosbie of Ardferd Abbey), had expressed a very strong opinion from which I was sorry to differ. He said, “I am disposed to give the most liberal construction to this act. I think that every man in the county of Kerry, who is not rich, should be attended.” I said that my knowledge of Kerry was tolerably good, that outside the town of Tralee there were not six men who could be called rich, so that, according to Mr. Crosbie's motion, we'd all be entitled to be dosed (laughter). Of course it is the mere poor who are to be relieved—those who are not able to pay. Mr. O'Connell concluded by moving the following resolution:—“Resolved that this board persevere in their original resolution, by which they agreed to divide the union into four medical districts; as, on the most mature consideration, they think that number in every respect to be amply sufficient to carry out the objects of the act 14 and 15 Victoria, cap. 68.”

Dr. Purcell must say, with great respect for Mr. O'Connell, that four divisions would not be sufficient to carry out the purposes of the act. If the act of parliament was to be carried out, let it be carried out in the sense in which it was intended to be. He was sorry that Mr. O'Connell entertained such a terrible opinion of medical men, the Medical Charities Act, and the manner in which it was contemplated that it should be carried out. A very distinguished member of parliament, whose name Mr. O'Connell bore, and with whom he was nearly connected, had stated, in his place in the house, when the poor-law was being passed, that the only relief which ought to be carried out in Ireland was medical relief—relief for the sick, the maimed, and the blind.

Mr. O'Connell assured Dr. Purcell that he did not mean to cast the slightest disrespect on medical men. There was no one in the community who respected them more. He thought that they were the only professional men in Ireland who gave to a large extent their professional services gratuitously.

Dr. Purcell—I am sure that you believe that. Having been connected with a dispensary myself, I can say that it is physically impossible that one or two can attend over an area of eighteen or twenty miles. Though you may say your mountains and bogs are uninhabited, still if there be one or two families at either extremity, they must be attended to, and the physical labour of the medical officer must be the same. Even supposing the population few, the distances are very great in the districts as struck out by the board. The population in the town of Killarney is very large, and in every district we have struck out, it is large. If the population be poor, as Mr. O'Connell says, they must be attended to. Medical relief as administered under the new act, would be found economical in its results; because if the head of a family heretofore got say, fever, and didn't choose to come in here, and that he died, the entire family were thrown on you, when, if a little timely medicine—a dose of salts, or some other simple medicine—were administered, he might have been restored before disease set in, and the union saved a great deal of expense.

Mr. C. Murphy, as one of the minority who voted for more divisions than four, and would now vote for six in preference to five, thought it right to say that, from his knowledge of one part of the union—the western division—he looked upon it as morally impossible for any one man to do justice to the poor sick. It extended from Beaufort-bridge to the bounds of Glanbeigh, in the Cahirciveen union, cutting cross, at the same time, from Beaufort-bridge to the Maine, and taking in Drummin and Miltown divisions, thus doubling the road to the medical officer, if he had two calls. He was an advocate for more divisions than the majority of the board had determined on, not from any partiality for the doctors, but because he was convinced that one doctor could not, for instance, do the business in the division to which he referred. If a woman was in labour at the foot of the Reeks,

and another at Castlemaine, how could one man attend both? Or if there were two cases of fever, one at either extremity of that large district, how could one man attend them? He was a heavy ratepayer, but still he was an advocate for the poor having the benefit of the act, or having it done away with altogether. He would, therefore, move, as a compromise, that Dr. Purcell's proposition be adopted.

Mr. Morrogh Bernard would ask Mr. Murphy, if there were four women in labour, at the four extremities of the division, would he be for appointing a medical man for each (laughter)?

Mr. Murphy said gentlemen might laugh; but he, for one, was not for saving the rates at the expense of the lives of the poor.

The Chairman said that we should accede to as many districts as we conscientiously believe would extend the relief which the legislature intended, but not an iota beyond it; for we are not here for the purpose of cutting out situations for a swarm of medical gentlemen—subsidizing professional men with public money, to enable them to make up for the deficiencies of their private practice. When we come to consider the working of this act, I will draw your attention to the importance, as a board of guardians, delegated with a power which, so far as finance is concerned, is very extensive—the importance of discharging your duty as guardians by, in every instance, adhering to every possible economy, and not to permit, by your vote, the expenditure of one shilling of the public funds except where the necessity is clearly demonstrated. Now, let me ask on what data are we to be governed in coming to an opinion as to what number of districts we are to fix on for the purposes of this act? What data can the Commissioners or the guardians go upon except those of population and area? Now, I am in a position to state that in an area of a hundred thousand acres there is not a human being living. Take the extent of the union—go to the west, commencing at the Reeks, and continuing on by Tomies, Glana, and on by Mangerton to the Paps, and though some of those tracts may be inhabited at the bottom, there is not one inhabitant in that area of 100,000 acres. There are 10,000 acres under water, and 100,000 acres of mountain uninhabited: so that the real area we have to deal with is a habitable area. No one expects that the doctors will administer medicine to the fish in the water, or the deer on the mountain. But the habitable extent of this union, compared with other unions where only four medical districts have been formed, is far less—for instance, Tuam. Their relievable population is 19,000 more than ours. I think, then, that I have laid before you data going strongly to show that we have not taken an unfair view of what we consider the necessities of the union, in recommending only four districts. I am glad that Dr. Purcell has come down, because, whatever be the result of this discussion, it has given us an opportunity of stating to him the reasons why we have come to the conclusion that four districts are sufficient for the wants of the union under the act: so that it is upon no light grounds that he will call upon us to alter our views. On reference to the debates, I have seen that, while the poor-rate in England averages over the entire of the most prosperous country in the world but 2s. in the pound, the average in this unfortunate country is 4s. All the taxation, for all purposes connected with local matters in England, is 2s. 3½d. in the pound: in Ireland, the average over the entire country, including the more prosperous parts of Ulster and Leinster, is 6s. 8d. in the pound. Notwithstanding that fact, you'll hear Irishmen outside, and English members stating we are anxious to avoid our just liabilities.

Mr. Gallwey—As the Commissioners have sent down an officer to state their dissent from the views maturely come to by the board, perhaps he would explain the grounds of that dissent.

Dr. Purcell—I consider the population too great—the area too great—for four medical men.

Mr. Gallwey—The extent of the population to be taken into account under the act. It appears now, from the statement made, that 110,000 acres should not be taken into account.

Mr. Richard Maybury said that there was one matter with regard to the parties entitled to relief under this act which the guardians should very deliberately reflect on, and which should have considerable weight with them, in coming to a decision on this question. The act says the parties entitled to relief are the sick poor, and he (Mr. Maybury) had no hesitation in coming to the conclusion that such a clause embraced artisans, mechanics, and all others rated under a £4

valuation. That class would compose the entire population of all the lanes in Killarney, besides a vast number in the rural districts. The relief given under the old law, was administered from no less than six dispensaries, which were in full operation up to the 1st of November last in this union. That relief was considered insufficient; and surely if these were inadequate, how much more so would four dispensaries be now? Sickness was becoming prevalent in the rural divisions, on account of the cessation of those institutions, and loud complaints were already heard of the delay in affording this union the benefits of this act. Those best acquainted with their wants—the Roman Catholic clergymen—had expressed themselves to the effect, that medical relief was absolutely necessary; and he (Mr. Maybury) had no stronger authority to appeal to as to the misery created by the continued absence of those medical charities. It was true that a large portion of this division comprised a considerable surface of bog and moor; but that was an additional argument for dividing the union as suggested by the Commissioners. The board should bear in mind this fact, that where a medical officer had to travel over fourteen miles to the extreme end of the district to visit a sick patient, it entailed a far larger amount of physical labour than if he had to attend to a large number congregated in a small space. He (Mr. M.) agreed with Mr. Murphy that there were some persons in this country who regarded the safety of their pockets more than the interests of the sick poor; but it was now for the board to show to the Commissioners that they were anxious to make this law a *bona fide* law, and not a nullity, and by thus giving in their aid and coöperation, show their anxiety for carrying out the benevolent intentions of the legislature. Mr. John Brennan said the people were more healthy since the dispensaries were done away with.

Mr. Leahy—There were more people died from Knockacappal in this house, since your dispensary was removed, than from any other part of the union.

Mr. Bland said it is all very well to say that the cost will only be about 2d. in the pound. It will be a great deal more. I have just come from a union, where I saw an application sent in for a medical man, and the actual fitting up of what was once a *shebeen* house was £90. You'll see in your five or six districts sums of money laid out, not for the good of the poor, but for the profit of young doctors.

Dr. Purcell—£90 for the fitting up of a house was a humbug, and should not have been allowed.

After some further discussion, Mr. O'Connell's resolution being about to be put,

Mr. C. Murphy moved an amendment that five division should be formed.

On a division the numbers were—for the resolution, 19; for the amendment, 9.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, APRIL 21, 1852.

### WORKING OF THE DISPENSARY ACT.

WE direct the attention of our readers to the discussion given in our columns this day (page 250) at a meeting of the Tralee Board of Guardians. It touches so many disputed points that it is well to see how the parties deal with them, and the defence set up for some questionable views respecting the intent and meaning of the act. The Guardians and Commissioners have evidently come to issue on the points disputed, and we hope that the latter will have the courage to insist upon obedience to the law. Dr. PURCELL, the Inspector, is entitled to approbation for his conduct on the occasion. He did his duty without provoking hostility, and showed a proper feeling of regard for medical interests without forgetting those of the poor or ratepayer. We entertain a sanguine hope that with a little firmness, a little argument, and a judicious appeal to facts, this measure will, in the sequel, be brought into more salutary operation than at present, but this can be achieved only by a resolute determination to construe it in a liberal

spirit; keeping in view the obvious conclusion, that the very best result of the Irish poor-law will be the restriction of relief to those to whose wants the medical practitioner ministers.

### PAYMENT FOR MEDICAL SERVICES.

WE again copy some observations affecting this question which appear in a London contemporary, because we are convinced that the time has arrived for a free inquiry into the cause of the evil consequences of gratuitous medical services in public institutions. There is no use in concealing it, the time has passed when character acquired in the hospital or lecture-room had its reward in the shape of lucrative practice, and when men were well paid for their early labours by later returns. Whatever the cause may be, it is now a notorious fact that "the public" are to be propitiated by very different means, and therefore that this excuse for trespassing on private property can no longer be accepted. The unfair advantage taken, even by persons calling themselves statesmen, to extort gratuitous services from medical practitioners, is even found an impolitic resource; and men of common honesty and common sense agree that, in every other calling, "a fair day's wages for a fair day's work" is after all the best bargain. In this view we surely are bound to concur, and therefore should we practically enforce it. How can our brethren in the provinces assert a right to proper remuneration when those in the metropolis accept salaries merely nominal?

The question of the payment of the medical officers of hospitals cannot be considered as an isolated subject. It is one intimately connected with the entire economy of our great public hospitals, and the medical schools which have grown up within them. It appears that the old and richly endowed hospitals—the royal charities, as they are termed—without, we believe, an exception, pay their physicians and surgeons, and their assistant-physicians and assistant-surgeons. We entertain little doubt, that the attention now directed to this subject will lead to the adoption of the principle of remuneration in the case of those hospitals whose funds are sufficiently ample to warrant it. No doubt much wrong has been done by leaving medical men to be the very last servants of rich hospitals to receive remuneration for faithful, arduous, and even dangerous service. But when the lawyer and the divine are well paid, the medical man cannot long be asked for gratuitous service. To name a special instance, we see the London Hospital has just advertised, that, in order to obtain a clergyman of high talent and standing, the governors are about to increase the salary of their chaplain. Now, the London Hospital is one of the non-remunerating hospitals, though it possesses a splendid income; but surely after parading a liberal hand towards the divine, this hospital cannot continue to play the niggard towards the medical man. It is, however, unfortunately too true, that there are several of the metropolitan medical charities whose funds are in such a low position that payment to medical officers is out of the question. They are obliged to shut their gates against the destitute sick and diseased, not for want of room, but for want of funds. It is a well known fact, that, compared with its size and population, the hospital accommodation in London is inferior in extent to any other capital city in Europe. This truth is a severe censure upon our boasted philanthropy. Nor is this all. Even the accommodation we have is not available, for lack of money. There are hospitals, wards, and even beds, waiting; but there are in many cases no means to furnish nurses, and food, and medicines for the suffering sick. Let the empty wards and beds of University College, Charing-cross, St. Mary's, the Royal Free, and, we believe, the Westminster Hospitals, attest the truth of this. It is, indeed, a crying shame and scandal to an age of charity like this, that the means of health and blessings which our great general hospitals possess, should not be fully employed. But is there any cause for this in which medical men themselves play a part? From a mature consideration, we fear we must reply that there is such a cause. We believe we see it in the tendency to fritter away charit-

able energy in the formation of bastard hospitals and dispensaries for the treatment of special diseases, having certainly no especial claims to isolation from general medicine and surgery. The instances are indeed few and rare in which special charitable medical institutions should be tolerated. These exceptions are pretty nearly exhausted when we mention syphilis, consumption, and the diseases of children. But even these divisions are running individual riot. There is not one hospital for consumption, but a dozen hospitals, infirmaries, and dispensaries, contending for the alms of the charitable in this particular disorder. There are also nearly a dozen hospitals and dispensaries for the diseases of women, crying out loudly for contributions in all directions. These things are a real injury to the cause of charity, and a great damage to the general hospitals, which, if efficiently organized and placed in full development, would do infinitely more good to the poor, and conduce with greater certainty to the advancement of medical science, than a thousand of the mushroom institutions we have been contemplating. The scores of pseudo-charities which infest the metropolis, and which are daily increasing in numbers and the impudence of their claims, consume charitable money to an enormous extent. It is well known that the economy of relieving the sick is only perfect in large hospitals. The amount of expense per bed diminishes in a remarkable degree after the first hundred have been provided. There can be no thrift or economy, but the direst waste and extravagance, in the petty places now dignified by the name of hospitals. They must all have their house-rents, collectors, secretaries, advertising and printing expenses, domestic servants, &c.; so that of the guineas given, but the smallest fraction reaches the bodies of patients in appliances of food and medicine. Here, then, we believe we have hit one of the blots of the age, and one which can only be remedied by the force of medical opinion. Medical men can, if they please, so influence society, that the streams of charity shall flow in deep and fertilizing streams, instead of being spread over a vast surface without producing an adequate result. There would then be no empty wards, no ranges of empty beds, deforming our great hospitals; and hospital physicians and surgeons might reasonably expect the day of remuneration to arrive. There is another point of immense importance in our hospital organization, which should not be lost sight of—namely, the mode in which the appointments to these institutions are filled up. Canvassing, favouritism, testimonials, cliquery, are every day becoming more and more odious. The despotic hand which now rules France has just swept away the “concours,” under which the French School of Medicine has risen to a high grade of dignity and perfection. Possibly, now this system of election has been banished from the sister country, it may find more favour here than it has hitherto received. Englishmen may now begin to detect its virtues. Practically, the germ of the concours, or its analogue, has already been adopted in this country; and we are much mistaken if its development does not force its way through the barriers which surround it. We give away prizes, medals, scholarships, fellowships, and even house-surgeonships, by competition; and this only need be extended to the appointment of physicians and surgeons, to render our system of election perfect. This reform would be a greater change upon the present system, than the present upon the past, in our hospital elections. If we could only establish the concours, and reform the condition of charitable feeling in this country, our hospitals and medical schools would rise to unparalleled usefulness and prosperity, the realm of medical science would be enlarged, and a vast benefit would be reflected on every man engaged in the practice of medicine in every grade and department.—*Lancet*.

#### THE PHELAN TESTIMONIAL.

WE have had a flaming epistle in the way of a “reclamation” from “the Secretary” of Mr. DENIS PHELAN’s Committee, taking to task our brethren in Cavan, who very naturally disclaimed association with him in his generous undertaking. But as our readers may prefer an appropriation of our space to some more useful subject, and as “the Secretary” has no personal claim on our columns, we must decline the honour of providing print and paper gratuitously for his use. It is quite enough to state that he says he is not the corresponding officer of any association, but only of a committee, and that Drs. ROE, COYNE, and

BABINGTON, “deliberately shut their eyes to the truths” contained in certain replies he has had to his circular, “highly creditable to Mr. PHELAN.” Moreover, he reminds us that these gentlemen could not be suspected of a connexion with any association or committee of the kind, seeing that they never were fortunate enough to be Workhouse Medical Officers. Nevertheless, we think the gentlemen in question exercised a sound discretion when they removed all doubt which might have existed as to their possible coöperation in the proceeding. In addition to this, we have, however, an assurance that the Secretary has received replies to his circular calling for the same, which “constitute an amount of independent evidence from men of high education and standing in the profession, of every shade of political feeling, and of various religious persuasions, that is most highly creditable to Mr. PHELAN, as an officer who had arduous and important public duties to perform, and which cannot fail to prove highly gratifying to his feelings.” Doubtless he has received these replies so flattering to the object of his veneration, for it behoves Medical Officers of Workhouses to cultivate amicable relations with Poor-law Inspectors. We believe some of them have had practical experience of that. In these troublesome times no one can tell what changes may take place, and therefore is it prudent for a man to have his name on no black list. As “the Secretary” says, “he is sorry that we, in giving the address to our readers, did not also lay before them his circular, which accompanied it, as forwarded to the Union Workhouses,” we here append it, commending the whole affair to the special notice of the Commissioners as a valuable illustration:—

DEAR SIR,—The committee appointed to prepare an address to Mr. Phelan, a copy of which I enclose, request your coöperation in carrying forward this object. They desire me to request that you will be good enough to assist them in procuring the signatures of such medical officers as are now, or may have been, in charge of the auxiliary houses of your union; the names of these gentlemen not being known to me, I am precluded communicating directly with them. As this address will be presented at the earliest moment possible, you will perceive how desirable it will be that I should have your signature, and those of your former and present colleagues, at your very earliest convenience.—Yours very faithfully,

CHARLES HALPIN, M.D.,

Secretary to the Committee.

Cavan, March 20, 1852.

#### MEDICAL BLACKGUARDISM.

WE believe that while there is a vast amount of honest and respectable practitioners in England, there is also, judging from advertisements, a fair proportion of what in vulgar parlance are called “dirty fellows,” of whom the author of this advertisement is one:—

A medical practitioner will shortly require the services of a gentleman (*not Irish*) as visiting assistant, who must be of active habits, obliging disposition, and courteous manners, of good attainments, and fair professional experience. Address to X. X., care of Mr. Rivers, Apothecaries’ Hall, Blackfriars.

We venture to say that this insulting libel on Irish Surgeons has had its origin in some sore personal irritation, probably castigation for some brutal exercise of authority. In another case, in which this gratification of spite was resorted to, we ascertained that jealousy was the provoking cause; whether it has been so here time will tell. But who is this Mr. RIVERS of the Apothecaries’ Hall; is he an official of the Company? If so, the sooner he is compelled to answer for such gross conduct the better: for until he gives up the name of his employer, his must fill its place. We entertain no fears for the characters of Irish Surgeons

in England; with but very few exceptions, they have proved themselves worthy of confidence, and whether as assistants or principals, have given general satisfaction. There is doubtless a strong anti-Irish prejudice prevailing at the other side of the channel, but we do not believe that it prevails in the medical body.

### THE FOUNTAINS OF MEDICAL HONOURS.

It is evident that "the doctors," like all the rest of the world, are about to be subjected to severe trials. The days of gold-headed canes, cocked hats, and full-bottomed wigs have long since passed, and now the virtue of caps, gowns, hoods, and bands comes to be tested. The transcendent qualification of a little Latin (and that none of the best), still less Greek, and a smattering of "Science," is profanely questioned, and the long-cherished delusion touching academic infallibility is irreverently exposed. *Ecce signum!*

A general feeling, which the fellows of the College of Physicians will do well to take into account, prevails against the proposal to make the fellowship of the college, under a new charter, a matter of examination. There is, and can be, no such difference between fellows and licentiates as should fairly be tested by examination. Indeed, we have heard it admitted by influential fellows, that they mean the examination to be used merely as a power of veto against the admission of improper persons to the fellowship. Certainly, classical acquirements will be no surety for the absence of quackery or the presence of high professional principles. As matter of experience, it is not the Dons of scholarship who treat medical science with the greatest respect. We would undertake to show that the foremost dupes and patrons of the present day are men of rank and station, educated at our old universities, where everything which relates to physical science is necessarily at a low ebb. The mesmerists boast that they number in their ranks the first classic, the first logician, and the first mathematician of the age. Of the present fellows of the College of Physicians, there are at least two who have fallen into condign disgrace, and one is a member of the University of Cambridge, the other of the University of Oxford. We object, then, upon principle, to any semblance of a return to the old system of favouring physicians educated at Oxford and Cambridge. Such a plan would debilitate the College of Physicians when an infusion of energy and vigour is sadly needed.—*Lancet*.

### CORRESPONDENCE.

#### DIFFICULTIES OF POOR-LAW MEDICAL RELIEF.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—For my own information and that of my fellow pilgrims, you will oblige by answering the following queries as far as may be in your power:—Suppose a medical attendant to a dispensary, is in attendance on a lady, preëngaged, in her confinement, or on a rich farmer's wife—rare occurrences in these days—and that a ticket is forwarded to him to attend a poor woman in labour, or any other urgent case, or if he is engaged as above, on a dispensary day, when many persons may be at the institution, or, if on a day of meeting of the dispensary committee, how is he to act? Or what view might the inspector take of it if he happened to pay his visit on such an occasion? These difficulties could be in a great measure obviated by allowing the medical officers a sufficient sum to enable them to keep assistants; one of which, even a boy who served a year or two behind an apothecary's counter, could not be had less than £20 a year, with diet, washing, and lodging, which would amount to at least £25 per annum. Add to these, £40 for wages, board, and lodging for a servant, and the support of a horse; take these items out of the £60 or £80 a year salary, and it will leave a man less than nothing to live on, and support his family. It would appear that the boards of guardians want to metamorphose us into cameleons, thinking that we can live on the air, and that we can have one of the attributes of the Deity—that of ubiquity!—Your very obedient servant,

A MEDICAL OFFICER TO A DISPENSARY,  
AND SUBSCRIBER TO THE PRESS.

Aye, here is the rub. The State will not pay for the

entire services of the Surgeon in the civil service as it does in the fighting service, and if it does not it must not have it. The Dispensary Surgeon will assuredly "do his best," but he must live by his private practice, and that must therefore be his first consideration. Be this as it may, we do not like to see so soon any leaning toward a submission to the views of Inspectors. These gentlemen will doubtless do their duty as becomes them, and we anticipate no superfluous exercise of their authority; if we did, we should recommend very decided resistance to anything of the kind. Here is an extract of a letter from another quarter:—

In Macroom, the union has been divided into four districts, and three medical men named at £40 each, and one at £50! There is work enough for six or eight. The Commissioners remonstrated with the guardians for allocating such inadequate salaries, and named £60 as the least, but the guardians have demurred; and on what grounds, think you, "because they had plenty of applications for the several posts at that low rate of remuneration." How can men expect to be respected, either collectively or individually, when one finds such competition as this? When the provisions of the law are at full work, you will find many resignations, as the office of dispensary surgeon in many districts, under such taskmasters, will be one of perfect slavery.

The following speaks for itself:—

The election of a medical attendant to the Finnea Dispensary, county Longford, was to have taken place on the 18th inst., but as no candidate offered, there was no appointment. £60 a year, and no prospect of practice, were the inducements. So much for the new dispensary law.

#### INSURANCE COMPANIES—"THE STANDARD."

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—My attention having been directed to two letters inserted in the MEDICAL PRESS, in which, amongst others, the writers include "The Standard" as one of those companies who do not pay medical referees, I take the liberty of referring you to the tenth page of the accompanying Report, in which you will find the following resolution by the Court of Directors, on the 10th of April, 1851:—

"MEDICAL FEES.—That the practice of the Company in future shall be to pay a fee to the medical attendants of parties referred to in connexion with proposals for assurance."

In justice to "The Standard," I have to request the favour of your inserting this letter in your next publication; and had your correspondents inquired at this office, they would have at once ascertained that their information was erroneous.—I am, sir, your obedient servant,

SAMUEL SMYLYE, Resident Secretary.

66, Upper Sackville-street, April 14, 1852.

We insert this with satisfaction. It is creditable to the Company, and we hope to see other companies following so good an example.

#### TESTIMONIAL TO DR. CONOLLY.

FEW men have deserved better of their countrymen than Dr. John Conolly. Under difficulties which to a less powerful and benevolent mind would have been deemed insurmountable, he succeeded in abolishing, in the County Lunatic Asylum of Hanwell, the cruel and unnecessary personal restraint to which the unfortunate lunatics had been subjected. The example was followed in most of the public asylums of the country, and now restraint may be said to be the exception instead of the rule. On the 7th inst., Dr. Conolly received from the hands of Lord Shaftesbury, and in presence of a large and influential meeting, at Willis's Rooms, a public testimonial to his services. That testimonial consisted of an excellent portrait of the benevolent physician, painted by Sir W. F. Gordon, R. A., and a magnificent piece of plate. Lord Shaftesbury, himself a philanthropist of no ordinary stamp, in addressing Dr. Conolly, spoke in terms of much feeling and commendation of the services he had rendered to his country. The reply of Dr. Conolly was at once modest and manly. It is an honour to the profession of medicine to number amongst its members such a man as Dr. Conolly.—*Lancet*.

## MEDICAL ETHICS.

*To the Editor of the Lancet.*

SIR,—It was my intention, in conformity with advice of several medical friends, to have treated Mr. Howard's charge against me as unworthy of further notice, but as you have thought the matter deserving of editorial comment, I shall, out of respect to you and your office, put you as briefly as possible in possession of the real facts of the case, from which you will learn that Mr. Howard has himself committed a gross violation of professional decorum; and your readers in consulting practice may be made aware out of how small a matter a person of his peculiar disposition can fabricate a charge of unprofessional conduct. On the 24th of February last, I was requested to meet Mr. Howard at the house of a small farmer, twelve miles from Norwich. On my arrival, Mr. Howard was not there, and I then heard, for the first time, that he had wished for, and expected to meet, another physician; but that the friends of the patient had (improperly enough) summoned me without apprising him of their intention. Mr. Howard soon after came in, and after a natural expression of surprise at meeting a stranger, we conversed upon and visited the patient.

It is unnecessary to go into the details of the case; suffice it to say, that in my judgment wine was imperatively called for, and that Mr. Howard not only agreed that a certain quantity should be exhibited between the time of our meeting, eleven a.m., and his next visit in the evening, but even gave directions as to the means of preserving the bottle from getting chilled. I mention this because, as will be seen, he distinctly told the friends that he had never sanctioned the wine at all—an incongruity which they did not fail to remark upon. He also agreed, in reference to my expressed opinion that mercurialization was not desirable, to give the calomel every four hours, instead of every two hours, as heretofore. Now comes the part of the history upon which Mr. Howard basis his charge against me of contravening the consultation, and which gave rise on his part to an exhibition of coarseness in reference to myself. Observing his gig at the door, I requested him not to delay his departure—not, as he would insinuate, in order to take advantage of his absence, but out of real courtesy to him; which courtesy, he may as well know, I extended by endeavouring to restore that confidence in his prior treatment which the friends plainly intimated they had lost. He had left the house but a few minutes, when a bottle of wine was decanted for the purpose of giving some to the patient, and, my carriage not being ready, it occurred to me to witness its effects on the pulse. I accordingly did so; and requested the same quantity—a full tablespoonful in water—to be repeated in three or four hours. This did not occupy five minutes, and as I was leaving the house, the question respecting inunction was asked, and the reply which appears in the correspondence given. I now left the house, little dreaming that in this manifestation of interest in our patient, I had done anything which the most capacious mind could find fault with. It is true, Mr. Howard was an entire stranger to me, except in name. On the evening of the next day, I was again requested to see the patient, and at the same hour. On this occasion Mr. Howard was not present, and I soon learned, to my sorrow, and no little surprise, that the treatment agreed to had been peremptorily suspended on his evening visit; Mr. Howard not only denying that he had sanctioned the wine, but giving utterance to the rude comments on the value of my services which appear in my first letter. So unwilling was I to credit the recital which was made to me with well-deserved indignation on the part of my friends, that I was at the pains to verify the statement by a separate inquiry from three witnesses. Nothing, obviously, was now left for me to do, but to insist, in my own defence, on the views of treatment suggested by me, and to express to Mr. Howard, jun., who joined me at my request, my sentiments respecting behaviour as entirely new as it was disagreeable to me. The next morning brought the letter in which my well-intentioned return to the patient's bedside is termed an "intrusion," and which, sir, I think you will admit, was not calculated to mollify the impressions of the previous day.

It thus appears that my "unprofessional" conduct amounts simply to this: That while waiting for my carriage, I, after Mr. Howard's departure, entered the sick room and witnessed the effect of treatment commenced at my suggestion, and agreed to; an act which few but Mr. Howard would, I imagine, have misconstrued at any time, but which in the present instance, was purely accidental, and would not have taken place at all, had my conveyance appeared five minutes earlier. I also incidentally stated, that we did not consider

inunction important, this appearing to me a natural conclusion, as we had decided that ptyalism was not desirable, and had ordered calomel at longer intervals. Whether this merits the accusation made against me, I leave you and your readers to decide, as I do to form your own estimate of Mr. Howard's part in the proceedings, which consisted in repudiating in the evening what he had acceded to in the morning, in coarsely commenting on my judgment, and in informing the friends that they "might as well have thrown their money into the gutter." The motive for such treatment of an entire stranger to him, I do not pretend to fathom. If (the only possible explanation which occurs to me) it arose out of annoyance that his own choice of a consultant was not acceded to, it was a most sorry exhibition indeed. I now quit the subject, and beg to apologize for thus occupying your valuable space. Such instances of medical disagreements are painful individually, as they are injurious to the profession at large.—I am, sir, &c.,

W. H. RANKING, M.D.

M. W. HANLON, M.B.

## MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE Annual Distribution of the Funds at the disposal of the Society will take place on the first Monday in June.

Applications for assistance must be made by printed forms, to be obtained from the Honorary Secretaries, and must be sent in to the Branch Associations before the 6th of May, or to the Parent Society before the 10th of May.

Branches are established in the principal towns of Ireland, and with Honorary Secretaries, as follows:—

Armagh, Dr. Colvan; Belfast, Dr. Stewart; Cork, Dr. Lloyd; Newry, Dr. Erskine; Waterford, Dr. Carroll.

The applications are to be forwarded to the Secretary of the nearest Branch, if any be near, or to the Secretaries of the Parent Society in Dublin.

Subscribers to the Parent Society are requested to send in their contributions as soon as possible to the Treasurer, Dr. Duncan, 19, Gardiner's-place, Dublin; and subscribers to the Branch Associations, to the Local Treasurers respectively.

By Order,

WM. KINGSLEY,

CHAS. BENSON,

Hon. Secs. Parent Society.

Royal College of Surgeons, Dublin, April, 1852.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

*Superior Dissecting Instruments well worth the inspection of the Student.*

#### THE COMPOUNDING DEPARTMENT AT

#### G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

#### BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

*Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

#### TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

#### BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than the Emp. Lyttae. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

#### BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

*Extracts and Editorial Note from the New York Journal of Medicine.*

“March 1, 1850.

“BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

“Accompanying this article is a very simple and neat dressing.”

*From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.*

“We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations.”

“Army Medical Department, January 16, 1847.

“The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

“ANDREW SMITH, M.D.,

Deputy Inspector-General of Hospitals.

“Mr. T. B. Brown, Druggist,

“Handsworth, Birmingham.”

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that on the 2nd of August, 1852, the Council will proceed to elect a Curator of the Museum from among the Fellows or Licentiates of the College.

Candidates will be required to lodge at the College on or before the 24th of July next, such Preparations, in Human and Comparative Anatomy, made by themselves, as they may consider best calculated to demonstrate their skill and abilities.

Information respecting the emoluments and duties of the office may be obtained by application to the Registrar at the College.

By order of the Council,

H. MAUNSELL, Secretary.

Dublin, April 2, 1852.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that on Tuesday, the 4th of May next, at the hour of Two o'clock, the President and Council will proceed, according to the provisions of the Supplemental Charter, to elect, from among the Fellows of the College,

Three Examiners in Medicine and Surgery;

Two Examiners in Anatomy and Physiology;

One Examiner in Materia Medica, Chemistry, and

Medical Jurisprudence;

One Examiner in Midwifery.

Candidates are requested to lodge their applications at the College on or before Thursday, the 29th of April.

By order of the Council,

H. MAUNSELL, Secretary.

Dublin, April 2, 1852.

#### SCHOOL OF SURGERY.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE Summer Courses of Lectures will commence on Monday, the 26th of April, when Lectures on the following subjects will be delivered, in accordance with the regulation of the Council of the College:—

Materia Medica	...	...	Dr. Williams.
Medical Jurisprudence	...	...	Dr. Geoghegan.
Practical Chemistry	...	...	Dr. Barker.
Botany	...	...	Dr. A. Mitchell.

Examinations will be held, and Premiums awarded to the successful Candidates, at the termination of the Session.

#### DISEASES OF THE EYE.

#### SUMMER SESSION.

DR. JACOB will commence his Lectures on Diseases of the Eye, in the City of Dublin Hospital, on Monday, the 10th of May.

#### CITY OF DUBLIN HOSPITAL.

#### SUMMER SESSION.

THE Clinical Lectures and other forms of Instruction will commence in this Hospital on the 26th of April. By a recent Ordinance of the College of Surgeons, separate Certificates of Hospital Attendance, during the SUMMER SESSION, are required.

#### THE LORD CHANCELLOR'S PRIZE.

This day is published, price 10s. 6d.,

INSANITY; its Causes, Prevention, and Cure; also Nervousness, Irritability, and Sleeplessness; showing the inestimable value of the Sedative Treatment, including Apoplexy and Epilepsy, and Inflammation and Congestion of the Brain. Second edition, much enlarged, and illustrated with numerous Cases.

By JOSEPH WILLIAMS, M.D.

London: John Churchill, Princes-street, Soho; and all Booksellers.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

### PARALYSIS OF ONE SIDE OF THE FACE AND OF THE OPPOSITE SIDE OF THE BODY.

By Professor BENSON.

DR. BENSON exhibited a morbid specimen, illustrative of a case which was lately under his observation at the City of Dublin Hospital. The patient was originally admitted, under Dr. Jacob's care, for an opacity of the cornea, the result of inflammation, accompanied by paralysis of the left side of the face. After a short time, he was placed under his (Dr. Benson's) care, at which period he was labouring, in addition to the foregoing affections, under epilepsy and paralysis of the right side of the body. These were the symptoms in November last, when he first came under his treatment; and on making an inquiry as to his previous history, it appeared that in the month of April, 1851, about twelve months since, he had a severe epileptic fit, which did not, however, leave any bad consequences behind; but that in the month of May following, he had another violent attack of epilepsy, after which he suffered very severe pain, extending from one temple to the other, or somewhat lower down, almost about the situation of the eyes, or inferior part of the forehead. Together with this state of things, there was a certain amount of loss of power of the right side of the body, but not constituting a complete paralysis. He was able to walk to the hospital for advice for the affection of the eye, of which he chiefly complained, and which was brought on by constant exposure of the organ, occasioned by the patient's inability to close the lids. When he came under Dr. Benson's care, he was unable to close the left eye; when gently touched over the left side of the face, there was no appearance of sensation, but he winced when strong pressure was made, especially in the situation of the branches of the fifth pair of nerves. Sometimes, however, the slightest pressure would give him pain, and at other times the strongest pressure would excite no sensation at all—so great was the irregularity of his sensa-

tions in that respect; but he appeared to have lost altogether the power over the muscles supplied not only by the fifth pair of nerves, but even those supplied by the portio dura. He was quite unable to close the jaw with force at the affected side, for he could not bring either the masseter or the temporal muscles to act at that side of the face, and when he attempted to laugh, whistle, blow, &c., the passive condition of the left side, and the activity of the right, caused the most ridiculous contortions of the countenance. The saliva dribbled constantly and unperceived from the left angle of the mouth, and when directed to put out his tongue it was pushed over to the left side.

The patient was aged 36, of the bilio-nervous temperament, dark hair, grayish blue eyes, thin, tall, of irregular and intemperate habits, and had had syphilis more than once.

The diagnosis which was formed and announced to the pupils, and which was afterwards found to be perfectly correct in every essential particular, was, that a tumour was pressing on the left side of the brain, by which paralysis of the right arm and leg was produced—that the tumour was of such a nature, and in such a situation, as to press either on the origin or course of the fifth pair of nerves and the portio dura of the seventh pair. It was not a complete hemiplegia of the right side, and therefore it was inferred that the tumour was not very large; just large enough to produce this incomplete paralysis, yet small enough to cause that kind of irritation which gave rise to the epileptic fits. In the course of some time, after partial amendment (which was effected by an issue inserted on the top of his head), this patient's health began to break down under the epileptic fits. A degree of stupor came on, in the course of the disease, which was subsequently explained by the post-mortem examination. He became stupid, insensible, and unable to enjoy his food; and he sank and died on the 14th of March.

*Autopsy.*—On the under surface of the dura mater, covering the upper and anterior part of the left hemisphere, a small flattened tumour was discovered, not larger than a hazel nut, pressing on the left hemisphere of the

brain, and producing, as they might suppose, the paralysis of the right side of the body. Another scrofulous tumour, of smaller size, was attached to the under surface of the dura mater, just where it rests on the surface of the Gasserian ganglion; this would account for the total paralysis of the fifth nerve, both in its sensitive and muscular functions. For a time he (Dr. Benson) was at a loss to know what was the cause of the paralysis of the portio dura, for it appeared to be healthy at its origin and in its course until it entered the auditory foramen, and there was, to all appearance, no disease in the petrous portion of the temporal bone. However, Mr. Carte, jun., was kind enough to lay open the course of the nerve, and then a tumour was brought into view which evidently pressed on the course of the nerve in its canal, and in that way led to its becoming paralysed. These tumours appeared to be all of a scrofulous nature. The other morbid appearances, observable in the brain, were a thickening of the arachnoid membrane covering the left hemisphere, together with an accumulation of serous fluid in the ventricles, and considerable enlargement of the glandulæ Pachionæ. There was nothing very new (Dr. Benson said) in the foregoing case; but he thought it worthy the attention of the Society as confirmatory of the views held by pathologists, with respect to the nerves implicated in the disease, and showing that they might diagnose with tolerable certainty the morbid appearances that would be found after death in similar cases, by analysing the symptoms, and setting its proper value upon each.

Dr. JACOB observed that the case just related by Dr. Benson was one of an instructive kind, as it showed them that pressure on the fifth pair of nerves might take place to the extent of inducing very severe neuralgia and loss of sensibility, without at the same time inducing sloughing of the cornea. There could be no doubt that division or destruction of the fifth pair of nerves, by diseases occurring in the situation mentioned by Dr. Benson, was often followed by sloughing and destruction of the cornea. But this did not occur in Dr. Benson's case, although sensibility was totally lost, and the neuralgia was exceedingly severe; and therefore it must be concluded that different degrees of compression on the nerves produce different effects. It was to disease of these nerves that they attributed the neuralgia that often occurred in those situations. In other cases they would find neuralgia, accompanied with a corresponding paralysis, from compression of the seventh pair of nerves, and in a third, sloughing of the cornea, caused by destruction of that nerve, probably one of the most unexpected results in the pathology of the nervous system. At the time this case was under treatment in the City of Dublin Hospital, he had a case in his private practice, in which there was a loss of sensibility at the left side of the face, with insensibility of the conjunctiva, total destruction of the cornea by sloughing, loss of the contents of the eyeball, and at the same time of vision. He had the materials of the case on paper, and had intended to lay them before the Society on that evening, but having omitted to bring with him the letter which he had received from the gentleman under whose care the case had originally been, and in which the writer had detailed the early history of the complaint, he would not dwell any further upon it until the next meeting of the Society.

Mr. BUTCHER inquired of Dr. Benson whether the small scrofulous tumour which pressed on the fifth pair of nerves was amalgamated with their structure, or was in connexion with the wall of the chamber in which the Gasserian ganglion was lodged?

Dr. BENSON said it seemed to be attached to the under surface of the dura mater, where the latter lay upon the Gasserian ganglion. It was, however, so closely united with the Gasserian ganglion, that on dissecting it off, the ganglion was necessarily injured. Though evidently belonging to the dura mater, it was in some degree amalgamated with the Gasserian ganglion.

Mr. BUTCHER thought the tension of the membrane which covered in the ganglion so great that no tumour on

the upper surface could produce pressure on the ganglion itself, but on the contrary, would press upwards, and give rise to pressure on the hemisphere.

Dr. BENSON remarked, that there was one phenomenon, connected with the paralysis of the right side of the body, which perhaps showed that the disease, going on in the eye of the affected side, in these cases, was not altogether the result of exposure, but was, at least in some measure, caused by a want of proper innervation; for the patient, whose case he had described to the Society on that evening, had to a certain extent recovered from the paralysis of the right side of the body, as if the brain had become accustomed to the pressure, and thus allowed the paralysis to go off; but so long as the paralysis continued, spots were produced on the parts affected by the slightest degree of pressure, and abscesses formed on the elbow, shoulder, and other places, showing the tendency, on that side of the body, to run into disease; and in all probability, the same result took place in the eye, independently of the bad effects from exposure to dust, and other injurious influences, to which, they knew, it was submitted during paralysis of the orbicularis palpebrarum, which was not the effect simply of exposure, but of want of sufficient innervation.

Dr. JACOB—You may have a sloughing of the cornea, however, where there is no paralysis in any part of the body.

#### TWO CASES OF SUB-CONJUNCTIVAL DISLOCATION OF THE LENS.

By S. T. CHADWICK, M.D. Edin., M.R.C.S.E., &c.

THE two following cases of sub-conjunctival dislocation of the lens recently came under my observation, the history of which I transmit to you for insertion:—

William H—, aged 55, by occupation a hand-loom weaver, and who resides at Tong, a distance of two miles from Bolton, came to market one afternoon, when, after transacting his business, and on his way home, he called in at a public-house to get half a pint of beer; he had scarcely sat down, when a man in a state of intoxication came behind him, and uttering an imprecation, he said he would "croak" him, meaning thereby that he would thrust out his eye; then introducing one of his fingers forcibly between the left eyelids at the external angle, which act produced a considerable degree of suffering, immediately followed by faintness.

I saw him in about an hour after the receipt of the injury, and found him complaining of great pain; there was already some tumefaction about both palpebræ, and the appearance of a few drops of blood having passed over the cheek, which had evidently escaped from the eye. It was with the greatest difficulty that I could prevail on him to allow me to separate the eyelids, and I had to desist, as the attempt aggravated his pain very considerably; consequently I was prevented arriving at anything like a satisfactory opinion as to the extent and kind of injury that had been sustained; there was sufficient evidence, notwithstanding, to satisfy my mind that serious injury had been inflicted on the visual organ.

I prescribed for him a grain and a half of opium, to be taken at bedtime, and the lotion of the solution of diacetate of lead, diluted, to be kept constantly applied by means of linen compresses. On the following day, I found the swelling considerably augmented, the pain more intense, so much so, that there was no possibility of ascertaining the state of the cornea or sclerotica. I ordered a mixture containing the sulphate of magnesia and the solution of tartarized antimony every four hours, and a pill composed of calomel and opium three times a day; six leeches around the orbit, followed by fomentations. This treatment was persevered in for a few days, and as the warm fomentations were more grateful to the patient's feelings, they were substituted in lieu of the evaporating lotion. On the fourth day, however, owing to severe circumorbital pain, accompanied by lancinating pains through the head, he was cupped from the neck to twelve ounces.

On the seventh day the swelling and inflammation had so far abated as to permit a more satisfactory exploration of the parts, which presented a considerable degree of sclero-conjunctival vascularity. The cornea was entire; the anterior chamber had a deep-red appearance, as if filled with blood, thereby preventing a view of the iris and pupil. At the external palpebral commissure, there were present marks of violence, as contusion, &c. About midway between the sclero-corneal junction and the caruncula lachrymalis, there was a swelling about the size of a horse-bean, which in two or three days subsequently became more prominent and defined as the chemotic condition of the conjunctiva began more rapidly to subside, so as to render it quite evident that it was the lens lodging under the conjunctiva. With Wenzel's cornea-knife I made a transverse incision over the tumour, when the lens, enclosed in its capsule and nearly transparent, escaped. Until this time the pain had been quite agonizing, although anodyne medicines had been freely resorted to. After this, however, the pain was very materially ameliorated, although he had frequent paroxysms, which were more frequent and severe towards evening, extending to the head and face on the injured side, for which he found relief from friction with a liniment containing laudanum, extract of belladonna, and strong mercurial ointment, twice a day.

A month elapsed before the anterior chamber cleared up sufficiently to convey any information as to the state of the iris, when it was evident that its superior half had been detached from the ciliary ligament, its only attachment being to the lower half of its circumference. The laceration of the iris from the ciliary body accounted for the hæmorrhage in the chambers of the eye. On the removal of the lens, strips of court-plaster and bandages were applied, as after the operation of extraction for cataract. The openings through the choroid and sclerotic, by which the lens had escaped, were soon perfectly united.

It is perhaps unnecessary to remark that the patient was kept in a darkened apartment, a strict antiphlogistic regimen enjoined, and slight ptialism maintained for a few weeks.

The eye, although several months have elapsed, shows no disposition to become atrophied. There is no useful vision; he can merely see the outline of large bodies, but cannot distinguish objects; which state of things is not to be wondered at, when we consider the slow but insidious and disorganizing inflammation which was going on in the texture for several weeks, besides the probable concussion the retina might have undergone at the time of the accident. I ought to remark, that about the time when the inflammation began to abate in the injured eye, the other became attacked with a sympathetic inflammation, which was so troublesome and intractable that fears were entertained lest he might lose useful vision of that also. By the ordinary treatment, however, after a considerable time, it improved, and he now possesses useful vision, although somewhat impaired.

The second case is that of Mr. Robert C—, linen draper of Little Lever. The account he gave was, that one evening, sitting before the fire, he went asleep; awaking in a fright, and in the act of rising from his chair suddenly, his foot slipped, when he fell forwards, his head and face coming forcibly into contact with a form, which was placed immediately opposite. On being raised, it was found that he had received a violent injury of the eye. A week elapsed before he sought medical treatment, his wife having used a variety of local applications, and given him strong purgative medicines, besides keeping him on a very spare diet. He informed me that the means employed had afforded him relief, and the swelling of the eyelids, which had been considerable, had nearly subsided. At this time the integument of the palpebræ and cheek was in a state of ecchymosis, there was redness of the conjunctiva and scleroticæ, the iris was inflamed, and the pupil irregular. The superior lid projected, which, on being raised, the appearance we observe in staphyloma scleroticæ presented itself. The tumour, which was circumscribed,

semi transparent, and situated at the superior part of the eye, a little above the junction of the cornea and sclerotic, had precisely the form of the lens. On making an incision through the conjunctiva, the lens did not immediately escape, as in the case of H—, but came away in two or three fragments, a portion of which had to be gently removed by the scoop. The ordinary treatment was followed up, and he made a rapid recovery, although the pupil is dragged towards the point where the lens was extracted, giving it an oval, irregular appearance.

In this case, likewise, there is no sinking of the eye; he has tolerably good vision, which is much improved by the aid of cataract glasses.—*Lancet*.

We do not think that the result of these two cases will go far to encourage surgeons to extract the lens because the eye has been severely injured. As to the lens escaping through a rent in the sclerotic and choroid and lodging under the conjunctiva, we are sceptical; and as to the virtues of "compresses" wet with a sugar of lead wash, we have our doubts too. Perhaps, after all, these unlucky subjects might have escaped as well under a disciple of Priessnitz or Hahnemann. A scrap of wet rag and some globules might have achieved as much as the heroic manipulations and remedies enumerated.

#### NEW METHOD OF TREATING FRACTURES OF THE THIGH AND LEG.

By CHARLES ROLLS, M.D., Wardsville, U. S.

I AM aware that, in recommending a new plan of treatment, in a case of surgery, on which there has been already so much dispute, and on which the medical profession, even at the present time, is much divided, I am entering on difficult ground, and one in which I shall probably encounter much opposition. But as I write in the hope of advancing surgical knowledge, and of suggesting an improved system of treatment in one of the most tedious and often troublesome cases which surgeons have to deal with, I trust that my remarks will be received in the same spirit with which they are penned; and if opposed, such opposition will be in that fair tone of criticism to which I shall be at all times ready to reply.

In fractures of the thigh, and frequently in fractures of the leg, I have in numerous instances been surprised and distressed to see how often the patients, even although under the best treatment which the country affords, leave their beds, on which they have been lying for weeks, to be deformed for the remainder of their life. I allude not to my own practice, nor to the patients of any practitioner in particular; but I doubt not every member of the profession will bear me out in the assertion, that cases of deformity are much more frequent than they could wish, and that after paying every attention in their power to their patients, they are often sadly disappointed by finding the limb, at the expiration of the time usually allowed for such fractures to unite, deformed, and their own reputation, perhaps, seriously injured. The question then arises—Is this deformity to be attributed to the fault of the practitioner, or is it the fault of the system or practice pursued?

This question I will first discuss.

Every surgeon, of course, knows, that there have been two modes, *par excellence*, recommended in treating fractures of the thigh: one, the bent position, as recommended by Mr. Pott, and most generally adopted by English physicians, and following in their wake the physicians in this part of Canada; the other, the straight position, as recommended by Desault, and generally followed by the French surgeons. Of course I feel great diffidence in opposing so celebrated a surgeon as Mr. Pott, and putting in my feeble dictum against a practice which has been so generally adopted by English practitioners; but after giving much consideration to the question, and considering it in every light, and under every point of view, I must say I do not think that Mr. Pott duly considered his arguments in

favour of that position before he promulgated them; nor do I think that the position itself presents sufficient advantages in the treatment to counterbalance the disadvantages which both patient and physician experience in carrying it out. Mr. Pott's arguments run thus:—"The muscles are the moving powers which disarrange a bone, after being set or replaced in its proper position. If these muscles be relaxed, they will have less power than when in a state of tension or extension to disarrange the reset bone; the bent position is the fittest for retaining the bone in its proper place during the cure." Now, there is one great point that Mr. Pott, it appears to me, has forgotten in these arguments; and that is, that if the bent position relaxes to a certain extent the muscles on the anterior part of the thigh, just in the same ratio does it extend or make tense the muscles on the posterior part; and therefore, supposing the power of the bulk of the anterior muscles to be equal to the power of the bulk of the posterior muscles, he will thereby lose as much as he gains. These arguments fall therefore to the ground.

Mr. Samuel Cooper, in his work on Surgery, perceived the force of this objection to Mr. Pott's plan of treatment; but being either convinced in his own mind, or else prejudiced in favour of the bent position, he comes to Mr. Pott's rescue, and thus argues:—"Reckoning up muscle after muscle, which by this position becomes relaxed, and then muscle after muscle, which by this position becomes extended or tense, he concluded by endeavouring to prove that in the most common part in which fractures of the femur occur, the amount of muscles relaxed are much more powerful than the amount of muscles made tense, and thus he justifies the position. Mr. Cooper's defence of the plan is plausible; but I am far from allowing that it is sufficiently reliable for us to found our treatment upon. I am not aware that the power of any particular muscle has yet been calculated; and I am very sure that the combined power of any number would be very difficult for the general run of surgeons to calculate, letting alone the difficulty they would experience in finding the exact spot of the fracture, and the exact number of muscular fibres inserted above and below that fracture.

There is also another point on which Mr. C. has forgotten to remark; it is, the course of the obliquity of the fracture, if oblique. This, every one who has studied mechanism will immediately perceive, will give much greater efficacy to the action either of the anterior or posterior muscles, according as the upper part of the fracture be anterior or posterior, internal or external; and therefore those muscles should be favoured whose action would in such case have the greatest power of displacement. But how are surgeons, generally speaking, to ascertain the course of such fracture? and if not, how can they calculate the exact relative power of the various muscles concerned? But taking it, for the sake of argument, for granted, that the bent position does relax a greater amount of muscular fibre than the straight, the next question which arises will be—Does the amount of benefit thus gained counterbalance the advantages thereby lost? I think not.

Desault, in his objections to the bent position, enumerates the following:—"The difficulty of making the extension and counter-extension, when the limb is so placed; the necessity of their applying them to the fractured bone itself, instead of a situation remote from the fracture,—as, for example, the lower part of the leg; the impossibility of comparing with precision the broken thigh with the sound one, in order to judge of the regularity of its shape; the irksomeness of this position long continued; the inconvenient and painful pressure of a part of the trunk, on the great trochanter, of the affected side; the derangement to which the limb is exposed, when the patient has a motion; the difficulty of fixing the leg firmly enough to prevent the effect of its motion on the thigh bone; the manifest impossibility of adopting this method when both thighs are fractured; and experience, in France, having been little in favour of such posture. He adds, moreover, what is gained by the relaxation of some muscles is lost by the tension of others."

Now many of these objections are certainly very valid; but the one on which I should lay very particular stress, and which I believe to be the cause of more deformities than the whole remainder combined, is that which related to the difficulty of correctly comparing the injured with the sound limb, and thereby forming a correct judgment (during the continuance of the surgical treatment) whether or not the limb has been placed and still continues in as correct a position as it should or could be. Take, for instance, the simplest case which can occur in fracture of the femur. Suppose there is no external damage, no unusual swelling of the part, no severe bruises,—a case, in short, of simple fracture, with a shortening of the limb, say one or two inches. The surgeon arrives; the patient is placed on a mattress of either hair or straw; the extension and counter-extension proceeded with, in the prescribed mode; the splints are adjusted, and every part of the operation completed as is usual when the bent posture is adopted. The limb has been measured and compared with the sound limb, as nearly as the surgeon can *guess* the corresponding spots (from which measurement has been taken) in the two parts; and all is supposed to be right. In two or three days the surgeon again calls: he finds the part of the mattress on which the nates lie has sunk, say half an inch to an inch; some corresponding movement must have taken place in the broken limb. The surgeon again measures the length of the limb, and discovers that the broken one does not so exactly tally with the sound one as at the time of setting it and his last measurement. However, the difference is but trifling, and he reasons with himself,—“It would be a great pity to unloose all the dressings, and extend and reset the part; and the patient may cast reflections upon himself; and perhaps, after all, it is all right; the difference in length may be attributed to the sinking of the mattress, and a slight change in the patient's posture,—and—and—and—.” Finally, he concludes that it is better to leave things as they are, and takes his leave. On his next visit, owing to the same causes, the difference in length between the sound and injured joint has not diminished, but rather increased; but the same arguments prevail in his mind to let Nature take its course. What wonder, then, if, when the patient rises from his bed, he finds one of his legs some inch or two shorter than the other, and that if he wish to keep up a gentlemanly appearance, he must henceforth wear boots or shoes with heels of different thicknesses, from one half to a couple of inches, or over. In such a case as the above, is it the surgeon or the system which is to blame? Perhaps a little of both; but in my opinion the latter much more than the former. For even had the surgeon, at his second or third visit, taken off all dressings and reset the bone, still pursuing the same plan (that is, the bent posture), he would be liable to the same disarranging causes, and would probably have to repeat the same process on every succeeding visit.

On account of these objections, and many others I might adduce, were I not afraid of increasing the length of this article too much for insertion in the journal, I am opposed to the usual practice adopted among English surgeons of using the bent position in cases of fractured thigh or leg. The question then arises, if the bent position be not the most advisable, is not the straight position, as recommended by Desault, likewise liable to many objections? I believe it is; although not to so many, by far, as the former position. Let us compare them.

The straight position is certainly the best for the purposes of making extension and counter-extension. The straight position is certainly the best for the purpose of comparison between the injured and the sound limb. The straight position is certainly the best for keeping the bed or mattress in an even and smooth state, which is better adapted to the coaptation of the limb and the comfort of the patient. The straight position is likewise better adapted to inform the medical attendant of the state of his patient at his periodical visit, as he may see, almost at a glance, whether or not any derangement has occurred since his former visit. On these accounts, were I constrained to choose between the two, I should prefer the straight to the bent position,

being satisfied it gives greater advantages both to surgeon and patient. But I am opposed to the practice of adopting either position (that is to say for a permanent one) during the whole period in which (in the accidents under consideration) the patient is confined to his bed; and I consider that if the position were, from time to time, changed from the straight to the bent, and from the bent to the straight, according as it might suit the feelings and wishes of the patient himself, it would be far less irksome and less painful to him, as well as conduce to his more speedy recovery. Let me explain myself more fully.

According to the usual treatment, after a fracture that is once set, the patient is expected to lie in the position in which it was set (be it either bent or straight), during the whole period of his recovery,—say seven to nine weeks. Does it not immediately strike every intelligent observer, that the weariness, the irritability, the restlessness, the utter exhaustion, and the sluggishness which consequently takes hold of the vital and reproducing powers of the system, must greatly and most materially retard the reparation of the injured limb? And is it not frequently to be ascribed to these causes alone that in many cases union never will take place? Is it not likewise perfectly apparent, that if, when the patient becomes weary and tired with one position, he be changed to another, it must greatly revive him; the pain and weariness of long confinement would be more endurable, and a more cheerful spirit and less of the repining one will present a prospect of more speedy recovery?

At this point some will, perhaps, be tempted to exclaim: "That is all very good, we well know that a frequent change of position must be very agreeable to a patient during a long and tedious confinement; but how is this change to be effected, without incurring great risk, and indeed almost a certainty of derangement in the fractured part, produced by means of such change of position?" I will now proceed to explain how; and in this explanation will be involved the new plan of treatment which it is the object of this communication to recommend to the profession for general adoption.

The apparatus necessary for the mode (which I am about to recommend) of managing either a fractured leg or thigh, consists of three ordinary splints, suited either to the leg or thigh, as the case may be; the eighteen-tailed bandage; cotton wool or tow; and a *long splint*, extending from the axilla to the sole of the foot, the construction of which is as follows:—The head of the splint (if I may so call it) is like the head part of a common crutch, only so small that the patient may lie on the bed without being inconvenienced by the under part projecting. On the inferior part is a piece of flat board, inserted on the extremity of the third or leg portion of the splint, and which fits to the sole of the foot, from the heel to the toes. Between these two extremities the splint consists of three portions: the body portion extending from the axilla to the hip-joint; the thigh portion extending from the hip-joint to the knee-joint; and the leg portion extending from the knee-joint to the sole of the foot. These three portions are connected with one another by joints in the hinge fashion, so that the thigh portion can be bent forward and upward toward the body portion; and the leg portion downward and backward toward the posterior part of the thigh portion; or in other words, after the splint has been fixed on the patient, on the outward part of the injured limb, the limb can be placed in the bent position usually adopted by the English surgeons, and the splint, by means of its action on the hinges, accommodates itself to the position, and supports and retains the part in such position. I would recommend practitioners to have two or three such splints, of different lengths, according to the different periods of life of his patient; for instance, one for young children, one for more advanced, and one for grown persons: each joint of the splint made in proportion to the relative lengths which the different parts of the body to which they have to be applied bear one to another. In the middle of each part is a slide, so that each individual part can be lengthened or

shortened to suit exactly the case under treatment. Immediately above the joint, at the hip, a broad leathern belt or strap is applied, long enough to buckle tightly around the pelvis; another at the knee-joint; and another at the ankle. Three small buckskin straps are affixed to surround the thigh, and three to surround the leg.

We will now suppose the patient lying in bed and all ready (in a case of fractured femur) for setting. I first arrange the long splint, by fixing it to the sound side, and either lengthen or shorten either or each of the parts (by means of the slides) as may be required. Laying it (the splint) then aside, the extension and counter-extension of the damaged limb is made in the straight position. Three splints, well padded with cotton-wool or tow, are then adjusted, one anteriorly, one posteriorly, and one internally; and all secured with the eighteen-tailed bandage. The long splint is then applied on the external part of the broken limb, and well padded, from the axilla to the foot, in any part where it may come in contact with the flesh; the straps around the pelvis, knee, and ankle are then tightened as firmly as the patient can conveniently endure; the small straps around the fractured part, either thigh or leg, likewise tightened, and a common roller bandage applied from the ankle to the toes, so that the sole of the foot shall be firmly and securely affixed to the foot-board which I have previously described. This completes the operation.

If the surgeon be a firm believer of Mr. Pott's doctrine of the advantage of relaxing the muscles, he may, if he please, adopt it for the first three or four days or week (according to the feelings of the patient), by gently bending the knee and raising it, and supporting the portion with pillows properly placed under it; neither need he fear, in case the long splint I have described has been firmly fixed at the different joints, and the bandage from the ankle round the foot and board beneath it keep the sole firmly fixed in its position, that any derangement will occur. But I recommend that the straight position, as a general rule, be maintained, if possible, during the first week; after that, if all progress favourably till then, there is but little danger of derangement from any muscular action around the damaged parts.

I am well aware that this point—viz., moving a fractured limb from the position in which it was set, will raise many objections among those who have always been taught that perfect rest and freedom from motion are absolutely necessary in the treatment of the fractures under consideration. I am free to grant, under the treatment usually adopted, it may be so; for what power, may I ask, have the short splints, which are in present use, to retain the parts in apposition. Certainly not enough to counteract the powerful action of the muscles, which action must have the direct tendency to drawing up, or, in other words, shorten the limb. If these short splints, therefore, only be used, perfect rest presents the best possible chance for a happy result in the case. But in the treatment before us, we have two fixed points—viz., the axilla and the upper surface of the board to which the sole of the foot is firmly and securely applied, and so long as the shoulder joint (if I may use the expression) is preserved on an exact level with the other side, and the sole of the foot is kept in close apposition with the foot-board of the apparatus, so surely must the limb be kept of one length, let the position be bent or straight; of course I need not add the condition, that the measurement must have been exact, and the splints arranged with nice tact and due judgment.

To recapitulate. I object to the bent position for treating these fractures under consideration for the many and solid reasons urged by Desault against its adoption; and further, because I am strongly of opinion that the weariness, irritability, and fatigue attendant (in all persons, but more especially in those of nervous, irritable temperament) on long confinement in one position, materially retards the regenerating process of Nature; further, because this position does not afford the surgeon the necessary facility for making an exact observation; and further, because

have seen so many deformities in cases treated under that plan.

I object to the straight position, as recommended by Desault, because of the weariness, &c., induced (similarly as in my objection to the bent position) by long confinement in one position; further, because although it might afford greater facility for the passage of dejections than the bent, it will not afford the same as can be adopted by the treatment I recommend; and further, because the long, straight splint, recommended by Desault, not having any fixed points of apposition, cannot keep the limb in a state of constant extension, such as I recommend, and which I am well convinced is the only sure method by which an exact union and a well-shaped limb can be, with any degree of certainty, counted on.

I recommend the new plan of treatment which, in this paper, I have endeavoured to bring before the attention of practitioners, because—1st. It will give them the advantage of setting the fracture in a straight position (which certainly is a great advantage), at the same time they may immediately after adopt the bent one if so inclined; at the same time, I do not recommend that position to be adopted before the expiration of a week, by which time, generally, the parts will have taken on a regenerating action. After this the positions might be varied to suit the feelings of the patients. 2nd. I recommend this plan, because of the great facility it will give the medical attendant to judge of the correctness in the length of the limb. Each time he visits his patient will have an opportunity of examining and comparing the length of the damaged side with the length of the sound one; and as long as the sole of the foot is placed in correct apposition with the surface of the foot-board, and the soles of both feet exactly correspond, the patient at the same time lying as straight on the bed as possible, and the upper part of each shoulder-joint being as correctly on a line as possible, so certain may be that the limb is in correct apposition, and the cure progressing favourably. 3rd. I recommend this plan of treatment because, as I before said, it will afford the patient, by being supported in the reclining posture, greater facility in the passage of his dejections. 4th. I recommend this plan, because of the very great relief it will afford the patient, by allowing him a frequent change of posture during a long and tedious confinement, and by this means conduce, at least in my opinion, to a more speedy recovery; and 5thly. I recommend it, because, with its other advantages, it combines that of continued extension, which Bichat so strongly recommends, and which I feel well convinced is the true secret of overcoming the resistance of opposing muscles, and of affording the best (I could almost say) the only prospect, in oblique fractures, of an exact and correct union of the fractured part.—*Upper Canada Journal*.

#### ACETATE OF LEAD IN EPISTAXIS.

By D. H. AGNEW, M.D., of Philadelphia.

DURING the month of November, 1850, I was called to see Mr. N—, who, with the exception of a very short interval, had been bleeding from the nose for four hours. No probable cause could be ascribed for the attack. When I first saw him, the blood was flowing quite rapidly from the nostrils, showing no disposition to coagulate. He complained of a sense of tightness across the forehead (not amounting to pain). The pulse, though small and quick, possessed a degree of firmness, which, taken together with other symptoms, induced me to believe the discharge to be dependent upon some temporary congestion of the vessels of the head. In accordance with this view of the case, the arm was tied up, and a quantity of blood, sufficiently large to make a decided impression upon the general system, abstracted; the head and shoulders elevated; cold applications to the former; a very stimulating pediluvium, with directions to draw into the nostrils occasionally a solution of sulphate of zinc and alum. This treatment, though it had the effect of diminishing for a short time the

hæmorrhage, failed entirely in arresting it, and before the lapse of an hour the flow became as great as at the commencement of the attack. The patient now began to feel the loss of blood very much, the pulse failed, the face became pallid, and the nervous system excessively agitated. It was now proposed to plug the nostrils, preparatory to any other measures for relief, but to this the patient obstinately objected. At this time the acetate of lead was suggested, from its known efficacy in controlling hæmorrhages from other parts. Ten grains were immediately administered in a little acetic acid, with directions to take a second powder, containing five grains, two hours and a half subsequently. Before the period came round for taking the second dose, the discharge had materially diminished, notwithstanding which it was given, and an hour following it had entirely subsided. The rationale of its operation seemed in this case to be beautifully and strikingly exemplified. The first effect was its sedative influence over the circulating system, apparent by the rapid diminution in the frequency of the pulse. Second, its sympathetic action (as I believe) through the medium of the nervous system upon the calibre of the capillary vessels of the Schneiderian membrane lining the nasal cavities, obvious in the diminution of the flow: and lastly, its effect upon the sanguine fluid itself, by increasing its coagulability. As a remedy in the different forms of profluvia, its value is well known to the profession; yet we think more decided results would be obtained were it administered in much larger doses than are usually recommended. I would not encourage the idea that caution in its use is unnecessary, though I do think the danger from its free employment greatly exaggerated. While writing, a case of uterine hæmorrhage occurs to me, where a fifteen-grain dose of the acetate of lead effectually arrested the discharge, and saved the patient's life, after the failure of every other resource, the lead among the rest, though exhibited in small doses. The precautionary measure of administering the article with acetic acid has not been neglected, and perhaps it is by thus preventing its conversion into the carbonate that no ill results have been witnessed. Seeing no similar therapeutical application of this agent, it is reported in order that it may receive a further trial.—*Phil. Med. Examiner*.

#### ON RETENTION OF THE CATAMENIA.

DR. MARCHAND mentions a case of a young woman, æt. 22, who had never menstruated, had suffered since the age of 13 or 14 from pains in the hypogastrium and loins. The pains recurred each month at the same period, and continued three or four days. During some years the abdomen had been tense, and for some time, the enlargement and the pain had gradually and considerably increased; the general health was, however, very good. On examination, it was ascertained that the external orifice of the vagina was closed by a membrane, behind which the menstrual fluid was retained. This membrane was laid open by a crucial incision; and after some blood had been forcibly ejected to some distance, there escaped two or three quarts of a black inodorous fluid, without clots. Compression was made on the abdomen. For three days the menstrual fluid continued to escape without pain, to the amount of four or five quarts; the abdomen diminished in size, and the patient seemed to be going on well, when she was seized, on the fifth day, with subacute peritonitis, of which she died nine days after the operation.

*Autopsy.*—The whole of the peritoneum beneath the transversalis muscle was in a state of inflammation. The convolutions of the intestines, slightly adherent to each other, were covered with false membranes, the serous membrane beneath being of a deep red colour, especially in the vicinity of the pelvis, where, and in the iliac fossæ, there was some pus or sero-purulent fluid. The uterus was longer than natural, about the size of a fist; the cavity of the neck was also dilated. The vagina was enormously dilated, especially towards the upper portion. The vaginal and uterine mucous membrane were tinged

with blood. The Fallopian tubes presented different appearances in their uterine and in their ovarian portions. The uterine part was normal; while the ovarian or abdominal end was distended with black blood, and resembled a varicose vein of the size at least of the little finger. The dark blood which they contained was very fluid, and could be very easily pressed out in drops through the fimbriated end of the tube. There were some drops of the dark blood on the portions of the peritoneum in contact with the Fallopian tubes; and at these points were the most evident traces of peritonitis.—*Archives Gèn. de Méd.*

#### CHLOROFORM IN PULMONARY CONSUMPTION.

By T. SPENCER WELLS, Esq., Surgeon, R.N.

MR. WELLS relates the following case at the request of a recently deceased nobleman, who had suffered during the last eight months of his life from attacks of difficult breathing and spasmodic cough. Most of the favourite remedies were employed with no relief to the symptoms; indeed, in some cases, with positive harm. Mr. Wells proceeds:—

At Rome, in May, the violence of the cough was quite extraordinary, and the fits of difficult breathing resembled those of pure spasmodic asthma. I was called to him in one of those fits just after having employed chloroform for another purpose. The thought then occurred simultaneously to his lady and to myself, to attempt, at any cost, to give some temporary relief. I accordingly threw a few drops of chloroform on a handkerchief and held it before his face. The most complete relief was afforded immediately. In a few seconds, he passed from a state of extreme suffering to one of perfect ease. Tolerably healthy respiratory murmur was heard in parts of the chest where loud cooing and whistling noises had been heard just before. From this time he would never be without chloroform in his room. He thought once or twice that it left a feeling of faintness, or increased weakness for some hours, and at one time, slight coldness and want of circulation in the extremities followed it; but I am not at all sure that these were not mere coincidences. They led me, however, to use the chloroform in a dilute form, mixing it with from four to six parts of eau de cologne. About half a drachm of this mixture on a handkerchief quite sufficed to afford relief, and as he did not take it at first more than three or four times a week, the quantity of chloroform inhaled was then very small; yet it always enabled him *immediately* to take a long, full, deep breath, and he described the sensation of relief as “most luxurious.” Latterly, as advancing disease led to a more frequent necessity for its employment, I thought the spirit in the eau de cologne might affect his head. I therefore gave the chloroform pure. Afterwards, the “dead feeling” in the limbs and increased weakness was never observed, although the quantity of chloroform inhaled was much greater. He never took it, however, in such a quantity as to produce anything like insensibility. He was always perfectly conscious, and knew the exact moment when the necessary relief was obtained. If he continued the inhalation longer, he felt himself becoming a “little light about the head,” and sometimes spoke for a few moments in a confused manner; but I never observed, at any time, the least ill effect which could fairly be attributed to the chloroform. The pulse always became fuller and softer, but its rate was scarcely, if at all, affected. During the last few days of his life, those well-known symptoms of ulceration of the trachea came on, which often render the termination of consumption so agonising both to the patient and his friends. They led to the more frequent and almost constant use of chloroform, but in the small doses, and with the same happy results. The intellect remained perfectly clear until asphyxia was actually commencing, and he was most anxious that those suffering from his disease might find relief from the same remedy. He called it his “bottle of life.” He was well acquainted with the physiology of respiration and circulation, was continually analysing his own sensations, and he said he felt perfectly sure, not only that the

chloroform relieved some spasmodic closure of the air-passages, and allowed air to enter his lungs, but that the vapour itself “ventilated his blood” more than common air would do. Its effect was always certain and immediate. We never had to *hope* that the remedy would be effectual; we were always *certain* that, whatever the degree of dyspnoea, however great the violence of the cough, so long as we had chloroform, the means of relief were at hand, and we were never once disappointed.

I do not wish to add any speculations to a narrative which I intend as a plain statement of facts, still less to deduce any general conclusions from one case; but I may add, that I have employed chloroform in two cases of spasmodic asthma with similar good effects, and that I have never been able to trace the least ill effect to its use. Even if it were proved to produce such injurious effects as opium and other narcotics, I submit that this would be no valid objection to its employment, for the daily general use of these drugs, the benefit of which is often very doubtful, shows that such ill effects are universally thought to be less than those likely to result from unrelieved cough and dyspnoea. I had more than one proof during the progress of the case just related, of the truth of the general belief, when, owing to accidental circumstances, no chloroform could be procured for some time. It must be remembered, also, that the period during which phthisis was running its course was much more than double the average length.—*Med. Times.*

#### GANGRENE OF THE LEG FROM ANEURISM OF THE AORTA.

WILLIAM GREEN, æt. 43, labourer, of Manchester, was admitted into the infirmary, January 23, 1852. He states that he has always had good health until thirteen weeks before admission, when he took cold and had inflammation of the lungs, from which he recovered. On the 21st of January, whilst going to his work, he suddenly felt a severe pain in the right knee, which quickly extended down the leg, and it became numb and cold. He went home, sat by the fire, and got some one to rub the leg; whilst sitting by the fire, so imperfect was sensation, that he allowed the limb to be burnt rather severely, and was not aware of the circumstance till it was pointed out to him. At the time of his admission the leg was red, cedematous, raised into large blisters, and traversed by red lines, extending as high as the knee. On the calf of the leg, where he suffered it to be burnt, there is a slough about four inches square, and another on the foot, of smaller extent. He has no sensation as far as the knee, but he complains of pain above on pressure nearly to the hip. Pulse full, quick, and irregular; has some cough and pain in the chest; perfectly sensible and answers questions rationally. Ordered one grain of opium every three hours, poultice to leg, also a febrifuge mixture; he was put on extra diet, and a full dose of opium given at bedtime.

24th. He was delirious during the night; inflammation active, and seems extending up the leg; bowels open; pulse quick and irregular. 25th. He is much worse; inflammation has extended up the leg, and he has no sensation in the limb above the knee; thigh painful on pressure, red lines extending upwards; pulse quick and weak. Continue remedies. Ordered vin. rubri, oz. vj. daily. 26th. He continues much the same. 27th. He is worse; has been very delirious; face sunk; abdomen tympanitic; pulse weaker; tongue dry. Ordered a mixture of bark, ammonia, and opium; beef-tea *ad libitum*. 28th. A somewhat indistinct line of demarcation begins to be perceptible below the knee; he is exceedingly restless and answers questions incoherently; pulse weaker and irregular. Continue remedies. 29th. He is evidently sinking; limb much the same. 30th. He continued to get worse; the line of demarcation is more distinct; he has delirium, hiccup, vomiting, and is sinking rapidly. He died about three p.m.

*Post-mortem twenty hours after death.*—Lungs inflamed, and very adherent; an aneurism of the arch of the aorta,

about the size of an orange, containing coagula, which were very loose: left ventricle was enlarged; abdominal viscera healthy; limb gangrenous to the knee. On laying open the large vessels a large clot of blood was found blocking up the popliteal artery, also another in the external circumflex artery, and one in the superficial external circumflexa ilei. Rest of the viscera healthy.

In this case there is no doubt that a portion of the loose coagulum from the aneurism of the aorta had been carried on with the current of blood, and being arrested at the spots above stated, cut off the circulation completely from the lower part of the limb.—*Prov. Jour.* [We suspect that some doubts may be entertained on the subject.]

#### MUSCULAR CONTRACTION—CADAVERIC RIGIDITY—FRENCH AND AMERICAN EXPERIMENTS.

It appears that the savans of Paris have been very recently engaged in physiological experiments upon muscular contractility and cadaveric rigidity; and they seem considerably elated, if not dazzled, by the new corruscations of light which these researches are supposed to shed in the realms of physiology. Whether this be, as it claims to be, a new burst of light, we will inquire into presently. In the meantime, we propose to give a translation from a French journal, narrating these discoveries, as reported by M. Leon Fourcault, on behalf of M. Brown-Séquard, as follows:—

According to the opinion generally received, post-mortem rigidity, which takes possession of the cadaver some time after the last breath, is wholly due to the mechanical effect of the coagulation of the blood in the animal tissues. The reasons given have, at least, considerable plausibility. Among those individuals suddenly struck dead, whose blood preserves its natural elasticity, rigidity of the muscles manifests itself with great force, whilst it is scarcely seen in those who die after protracted diseases, or after copious hæmorrhages,\* and still less among those who die asphyxiated by deleterious gases, the specific action of which prevents the coagulation of the blood. This contraction of the muscular system always disappears in advance of decided putrefaction, which destroys the organism, and subjects it to the reign of inanimate matter.

Hence, we are readily induced to admit two kinds of death: the one general, which supervenes first, at the moment when the heart ceases to beat, and which is in some sort only a displacement among the organic wheels of life, the intimate and harmonious action of which constitutes the unity of superior beings; the other variety of death supervenes subsequently in each individual wheel of the organism, as the consequence of the primary variety. Thus the general life may be abolished with the existence of the feeling or sentient unity, while, nevertheless, each organ preserves, during a time, a life of its own, after life proper; the persistence of which sustains itself above, and for some moments contends against, the reign of inorganic matter. To this last phase of life cadaveric rigidity belongs, which, so far from being considered as the result of a purely mechanical action, bearing testimony to confirmed death, is, on the contrary, the last manifestation of muscular activity: at the moment of actual death, the muscular functions act for the last time, without guidance or aim, until the vital principle is completely exhausted.

The system of experiment to which M. Brown-Séquard boldly submits the living organism, seems to us to have been dictated by analogous considerations to those we have enumerated, and the results which he has obtained favour the opinion that cadaveric rigidity is but life manifested in its utmost or last limits.

Having at first incidentally observed that the parts affected with this post-mortem rigidity (the assumed evidence of death) may, under the influence of sanguineous injections, become again supple, and give signs of irritabi-

\* This opinion is erroneous. The most copious hæmorrhage in the subjects of yellow fever does not prevent cadaveric rigidity.

lity, M. Brown-Séquard entertained this particular question, and, on varying his experiments, has arrived at the results which we are about to copy from him. In the dead bodies of rabbits and guinea-pigs (which become rigid in from ten to twenty minutes) he divided the aorta and cava in the abdomen, just above the bifurcation of these vessels; that done, he put into the ends of these divided vessels quills or tubes of glass, and by means of these he connected the vessels of the dead with those of the living animals of the same species, so that the blood of the latter was injected into the arteries and veins of the former, thereby establishing the circulation in the inferior limbs of the dead. This transfusion resulted in the removal of cadaveric rigidity in from six to ten minutes, and two or three minutes later the limbs responded by motions excited through muscular nerves.

It is then proved by these experiments, that the nerves and muscles which have lost their excitability, may have the latter reproduced by the influence of the blood, and even for a quarter of an hour after post-mortem rigidity had pervaded and ruled the muscles.

The same result was obtained by operating in another mode more simple and more easily repeated. A rabbit or guinea-pig was divided transversely on a level with the inferior borders of the kidneys, a ligature was applied on the aorta, which suppressed the vascular communication between the two sets of vessels; little by little the muscular activity declined in the inferior limbs, and was replaced, ordinarily, in less than half an hour by rigidity. After having been abandoned to this state for fifteen or twenty minutes, the ligature was removed, whereupon the circulation was reëstablished, and then, as in the preceding case, rigidity was removed, and excitability reappeared in the muscles and motor nerves.

Finally, in another series of experiments, M. Brown-Séquard investigated the voluntary motions and sensibility, with a view to ascertain whether they might not be reëstablished in limbs which, without having been separated from the nervous centres, could, nevertheless, be reduced to rigidity from the suspension of the circulation. With this view, he tied the aorta below the renal arteries, in vigorous rabbits; in less than ten minutes sensibility was abolished in the parts below, and in two minutes longer voluntary motion ceased; irritability still continued for nearly half an hour; afterwards rigidity took place, and was allowed to persist a quarter of an hour, at which time the ligature was removed, the circulation was restored, and, as had been expected, the blood brought back voluntary motion and sensibility.

These new researches bear out the following conclusions:

1. That rigidity in the cadaver does not prove that the muscles are dead.
2. That the motory and sensory nerves lose in the limbs all power to act where there is no circulation, but recover their functions from the action of the blood.
3. That the limbs of mammiferous animals, after having been kept for fifteen or twenty minutes in a state of rigidity analogous to that in dead bodies, can be restored to their normal state; that is, to irritability, sensibility, and voluntary motion.

The following account is evidently a continuation of the experiments of M. Brown-Séquard:—

On the 18th of June, 1851, at eight o'clock in the morning, an assassin, condemned to death for murder, was executed at the Barrier St. Jacques. His headless body was given to a celebrated physiologist, M. Brown-Séquard, for the purpose of trying an experiment on the transfusion of blood. He had, in operations upon animals, noticed that the muscles which were just becoming rigid, seemed to re-suscitate under the influence of fresh blood injected into the veins. The dead body preserved its muscular irritability until seven in the evening, when the stiffness, always consequent on death, seized upon the whole muscular system. As it was too late to obtain blood from the hospitals, and as that of animals seemed to promise but little success, M. Brown-Séquard caused an assistant to make an incision

in his arm, from which he took about half a pound of blood. This was passed through a linen cloth, and injected into the radial artery of the subject, a little above the wrist. The corresponding vein was opened, and the natural blood of the dead man, now perfectly black from want of oxygen, was made to yield its place to the fresh blood injected. By continuing the injection, it passed through the capillary vessels, from the arteries to the veins, and flowed up through the orifice cut to allow the old blood to escape. Though it entered of a brilliant red colour, it came out as black as the natural blood of the subject. But, being moved about in the air, it soon recovered its red hue, when it was again injected, to be still again disgorged by the open vein. In about half an hour the hand became sensitive, and moved convulsively under the discharge of an electric battery, which previously produced no effect. Out of the nineteen muscles of the hand, twelve recovered their natural irritability, or sensitiveness, and three of them contracted or expanded throughout their whole length. This state lasted from nine o'clock till midnight, when it began to yield to the rigidity natural to all bodies deprived of life. At six in the morning another experiment was tried, but neither the battery nor a fresh infusion of blood excited the least appearance of motion. The experiment seemed to decide, beyond a doubt, that in the human body, as well as in animals, the approach of rigidity may be deferred for a considerable period by the injection of fresh blood, and that by the further application of electricity, the muscles may be made to move as in the living subject.

In another journal we have met with a statement showing that the French savans regard artificial circulation as restoring to the dead both sensibility and motion, in part at least. But what is the test used to prove this "high argument?" Electricity! "Sous l'influence de cette circulation et au bout d'une demi-heure, la main de supplicé, par une sorte de resurrection partielle, redevint sensible et s'agit aux chocs reiterés des décharges électriques. Cependant tous les muscles ne se montrèrent pas également sensibles." (See 2nd L'Illustration, *Journal Universel*, Aug. 14, 1851.)

The fundamental propositions advanced in the above report, so far from being original and altogether new, are comparatively old. It is now a half a score of years since Dr. Bennet Dowler of New Orleans, not only investigated experimentally, and preoccupied the grounds recently taken by the French savans, but a vast deal more, without the aid of electricity. He has not restricted his experiments to the inferior animals, as dead guinea-pigs and rabbits, nor wholly to vivisections, but has experimented on hundreds of men, women, and children, without the all-powerful, but unphysiological, forces generated by electrical batteries.

The general views of life and death presented in the above report, were long since brought forward in Dr. Dowler's essays on contractility, animal heat, capillary circulation, natural history of death, and, in other papers, with copious experimental illustrations. His ideas and terms (so far as the two languages will allow) seem to have been adopted by MM. Fourcault and Brown-Séquard, as novelties.

It is unnecessary to allude to Dr. Dowler's vast collection of unpublished researches upon these subjects. Soon after his experiments began, he published various extended monographs with experiments illustrative of the duration, degrees, progress, renewal, and decline of contractility and muscular motion, including the conditions that might be supposed to influence the muscles, as the nerves, the blood, hæmorrhages, the temperature, rigidity, diseases, and under the most varied manipulations and modifying circumstances. The reader and the French savans have only to look into the medical journals of Louisville, New York, New Orleans, and of other cities at home and abroad, to be convinced that the news from Paris is old, and that Dr. Dowler's claims to priority of discovery are entirely indisputable. It is now more than

five years since Dr. Dowler (as he informs us) forwarded a number of copies of a pamphlet entitled *Experimental Researches on the Post-mortem Contractility of the Muscles*, to several members of the Academy of Medicine and of the Academy of Sciences. Indeed, Dr. Dowler's discoveries in the muscular functions must have been known as early as August, 1843. We have now before us a letter addressed to Dr. Dowler from the illustrious Louis, which we are permitted to use, and of which we subjoin a translation, showing that Dr. Dowler's paper entitled *Post-mortem Researches*, had been received in Paris more than eight years ago. Now, in this very paper is announced Dr. Dowler's discovery of the excitation of post-mortem contractility, by percussion, as well as several other discoveries, as post-mortem calorificity, post-mortem circulation, capillary action, &c. &c. :—

SIR AND HONOURED CONFREERE, — I know not how to thank you sufficiently for the extreme kindness with which you honour me in addressing to me the two pamphlets which you have printed; one on pathological anatomy, and the other on what you call sun-stroke. As to the subject of pathological anatomy, you have done, without doubt, that which no other physician has done till now; for it has been given to no person to make post-mortem examinations a few minutes only after death, when cadaveric rigidity (one of the most certain signs of death) exists as yet to no great degree. You have been able to see that which few persons have seen—to establish lesions susceptible of changing quickly; and, if you have been able to collect in detail, and until the last hour of the patients, the symptoms which they have experienced, you will do a thing very useful to science to publish what you have seen. As to what you call sun-stroke, the medical public cannot but read with a great deal of interest what you say; and for my part, sir and honoured confrere, I dare require you to pursue your researches in order to have complete certainty that the facts observed by you, or rather the deaths of which you speak, are truly connected with the consequence of the insolation. Permit me, in conclusion, to persuade you to continue your valuable labours, to study rigorously the facts which you have collected, as you yourself propose. Have enough confidence in yourself to make them known to the medical public, to whom they will be serviceable, and please accept, sir and honoured confrere, the assurance of my grateful and devoted sentiments. LOUIS.

Paris, August 5, 1843.

Dr. Dowler's method (percussion) and results are alike original. Physiologists had used, and they still use, electricity as the means of exciting muscular action—an agent of great power, one that produces irregular and convulsed motions in dead animals. Sir Charles Bell himself admits that results thus obtained are fallacious, "for the nerves, dead or alive, may convey the galvanic power, like a wet cord."

It is unnecessary to reiterate in this journal the results of Dr. Dowler's researches upon these subjects. It is sufficient to say that he has shown that the muscular force may be repeatedly excited, exhausted, and regenerated for many hours, and even after the appearance of post-mortem rigidity, without electricity, and after the removal of the nerves and blood. Cadaveric rigidity is often readily removed by art; and then, in many cases, muscular contractions will follow with perfect regularity, the cadaver raising his arm from the floor to his breast, carrying weights in his hand—after, as well as before, the removal of the brain, cord, nerves, and blood.

The French savans have, doubtless, been deceived, as well in the nature as in the originality of their experiments. They had exhausted, temporarily, the muscular by the electrical force; they then set about injecting the blood-vessels with fresh living blood; in the meanwhile the regeneration of the muscular force had been progressing, and had the operators injected no blood whatever, but delayed for an equal period, contractility would have returned; for the amputation of a limb, and the removal of the blood and bloodvessels, will not in the least diminish the contractility, though in the living state, Dr. Dowler has admitted that the blood and the nerves may contribute as auxiliary to the inherent forces of the muscles, being rather

the essential conditions than the essential agents of motion, both voluntary and involuntary.

We venture to suggest another source of error into which the French savans have probably fallen. They tell us that cadaveric rigidity having manifested itself in the guinea-pig, blood was thereupon injected, rigidity disappeared, and contractility returned. Now, we incline to think that it was the incidental manipulation of the animal, not the blood, that removed the rigidity; for Dr. Dowler's researches show, that in man and in the alligator, how much soever they may be mutilated, rigidity may be, by forced motions, removed repeatedly, after which contraction can be excited for hours, and in the latter for three days. The rigidity will take place repeatedly, if the body be left perfectly undisturbed for a suitable time.

Dr. Dowler's researches prove that sensation and voluntary motion may exist independently of the brain. The French experimentalists seem to show that both of these fundamental functions can be revived, for a time, by the transfusion of blood from the living into the dead, even after the rigor mortis. We wait for further proof, as the subject is not sufficiently ripe for safe speculation.

Let the French savans look at page 54 of the July number of this journal, where they will see, in Dr. Dowler's last contribution, a summary statement of the principal laws of muscular contractility, cadaveric rigidity, &c., deduced from experiments commenced eleven years ago.

With respect to this last contribution of Dr. Dowler (so fundamental, not to say revolutionary, in its bearings), we may remark, that, judging from sundry letters, and from notices of the medical press, so far as we have seen, its reception has been very flattering.

It has been urged, as an objection to Dr. Dowler's papers and essays, that they are not sufficiently practical in their spirit and bearing. To this we reply, that the writings of Hunter, Harvey, and some others, were looked upon by the less sagacious of their contemporaries as of little practical utility at the time, and too speculative in their tone for the age; but the lapse of years, and the researches of organic chemistry, have established as indisputable truths many of these then supposed speculations, and mankind are at this present moment receiving the benefits and blessings derived from the experiments of those illustrious minds. So, in like manner, we anticipate glorious results, at some future day, from the untiring labours and ingenious experiments of Dr. Dowler; and if we cannot apply to practical purposes—to the coining of money—the important discoveries in physiological sciences which our confere has from time to time published to the world, we indulge the pleasing hope that another generation will reap the full benefits of his labours, and render homage to his name.—*New Orleans Med. and Sur. Jour.*

#### CARBUNCLE AND SACCHARINE URINE.

JOHN BROADBENT, aged 66, of Manchester, packer, was admitted as a patient of the Manchester Royal Infirmary, December 12, 1851. At this time, he presented, on examination, a large carbuncle on the back of the neck; it had a quaggy feel, and when pressed pus exuded from numerous cribriform openings. His tongue was moderately clean, and his pulse weak. A crucial incision was made into the tumour, poultices subsequently applied, and a mixture ordered, containing bark, ammonia, and opium. He stated, on the question being put to him, that he thought the quantity of urine increased; it was ordered to be measured, and a portion reserved for testing the following day. The urine measured five pints, sp. gr. 1.031. Tested by being boiled with liquor potassæ, it produced the deep colour so characteristic of diabetic sugar. Boiled with sulphate of copper, and excess of potass, it yielded immediately the red oxide. A portion was put on one side for about forty-eight hours, and when examined by the microscope showed an abundance of torulæ.

The subsequent treatment was conducted on the ordinary principles of surgery. Tonics were given, with a generous diet and stimulants. Stimulating applications

were applied to the wound. The patient recovered rapidly, and in a few days not a trace of sugar could be discovered in the urine. The sugar remained for sixteen days after he came under treatment, in variable quantity, and continued steadily diminishing, as follows:—

Dec. 17, Urine	4½ pints,	sp. gr.	1.031.	
„ 21, „	4 pints,	„	1.030.	
„ 25, „	4 pints,	„	1.026.	
„ 29, „	3½ pints,	„	1.028.	Slight indication.
„ 31, „	less than 3 pints,	„	1.024.	No sugar.

John Owen, aged 62, of Manchester, green grocer, was admitted a patient of the Manchester Royal Infirmary, November 21, 1851. At the time of his application he presented a large carbuncle at the back of the neck. He was exceedingly ill; bowels confined; pulse weak and rapid; the tumour presented the usual venous hue and cribriform openings; it was freely opened. Ordered a stimulant poultice. A full dose of calomel given, the bowels well opened, and then a tonic mixture of bark, ammonia, and opium administered. The urine was ordered to be measured, and kept for examination. The man is improved this morning; the pulse has improved in quality, and the wound looks as well as could be expected; he has had some delirium in the night; urine measured five pints and a half, sp. gr. 1.034; the tests mentioned before were applied, and the presence of sugar easily demonstrated. There was nothing after this in the case particularly worthy of notice; the case improved rapidly under good diet, stimulants, and tonics, and the sugar disappeared from the urine in eight days. A trace was again to be found on the tenth day, after which no more could be discovered.—These cases are of interest as showing the presence of sugar, but a comparatively short time has elapsed since it was first pointed out, and it has been repeatedly questioned. In these cases there could be no doubt as to the existence of the sugar; it was freely poured out, easily found, rapidly diminished under treatment, and ultimately disappeared altogether.—*Prov. Jour.*

#### ON A NEW METHOD OF APPLYING CAUSTIC IN THE TREATMENT OF STRICTURE.

By JOHN L. MILTON, Esq., London.

In the present divided state of opinion in the surgical world as to the treatment of stricture, any contribution likely to increase our mastery over it cannot fail to be interesting. The following is a novel and simple mode of applying the caustic:—The general plan is to direct a small hole to be made with a pin in the extremity of the bougie, and into this is inserted the piece of caustic destined to be applied to the stricture; or else we have armed bougies.

The objections to these are, in addition to those which have made so many surgeons abandon them for the plan of fixing the caustic themselves, that in many cases, especially in the country, armed bougies cannot always be had recourse to, as they are not always to be had when they are wanted, and that they are more expensive. The plan of cutting a piece of caustic is not free from objections: it is somewhat tedious, and the caustic sometimes projects and comes loose. Not that I believe there is anything to be apprehended from this, unless it be very large, but it alarms both the surgeon and patient, and in some irritable strictures produces a very unnecessary amount of spasm and suffering. The plan I now propose is somewhat similar to Hunter's way of applying caustic to pustules in the eye. The place where the caustic should go being cut flat on the bougie with a knife, and then made a little rough, a piece of caustic is laid on a sixpence, and fused in the flame of a candle; the rough spot on the bougie is dipped in the fluid, and is instantly coated smoothly with caustic. It is then dipped in the tallow, and twirled gently round till this sets, so that it has a smooth button-shaped sheath of fat. All that is now necessary is to clear the way to the stricture with a large bougie, and then to pass down that which has just been armed. The advantages of this plan are—1.

That we can fix the caustic to any part of any bougie. 2. That we can regulate the quantity with the greatest exactness. 3. That there is no waste; for what is left on the silver cools and hardens, and can be used another time. 4. That the surface is smooth, and does not irritate the urethra. 5. That these bougies are simple, cheap, always attainable, and efficient, and that (the caustic being protected by the fat from the action of the air and moisture) they may be prepared beforehand during leisure moments. —*Med. Gaz.*

## REVIEWS AND NOTICES OF BOOKS.

ON TRUE AND FALSE SPERMATORRHŒA. By Dr. PICKFORD of the University of Heidelberg. Edited by Chirurgus. London. 1852. 8vo. pp. 82.

THIS brochure consists of a translation from Dr. Pickford's work, with an introductory chapter of some length by the editor. The object of its publication is partly "to expose and correct the gross fallacies which prevail respecting spermatorrhœa and its consequences;" and partly to aid in protecting "the victims of sexual hypochondriasis from imposition at the hands of quacks." The introductory chapter by the editor is devoted entirely to the latter subject; it commences with some remarks upon the causes which lead persons the subject of "diseases of the genital organs" to become the prey of advertising quacks and nostrum-venders, and upon the frauds practised by the latter.

"The task upon which I am about to enter (the editor observes) is the exposure of a monster evil of unparalleled extent, and based on as refined and systematic a course of deceit as ever was reared by mendacious and rapacious knavery, for the purpose of preying upon the credulity and sufferings of mankind. But great as is the ingenuity which the impostors I am about to expose possess, and prolific as they are in concocting, and persevering in carrying out their schemes of fraudulent delusion, it is more than questionable if they could ever have met with the success they have attained, did not the proprietors of both the metropolitan and provincial press (with a few honourable exceptions) admit their lying and beastly advertisements into their columns."

"It is undoubtedly, in a great degree, through the sordid concurrence of these guardians of public morals (as they sometimes style themselves), that this crying nuisance has hitherto been able to defy the execration of all right-minded men. Without such aid, those miscreants could never have obtained more than an obscure existence, and a very limited power of doing evil; for they could otherwise have aspired to no higher position, and no greater gains, than those obtainable by thrusting their filthy handbills into the hands of passers through the public streets, or by chalking their announcements in urinals and by-places. That the portion of the public press which lives, as it were, from 'hand to mouth,' should, for the sake of the large sums these quack firms pay for their advertisements, lend itself to so disgraceful a traffic, is not much to be wondered at, however it may be regretted. But that such papers as the *Morning Chronicle*, the *Morning Herald*, and the fashionable and aristocratic *Morning Post*, should be guilty of this species of panderism, is perfectly incomprehensible. That these papers should degrade themselves by throwing open their columns to such obscenity for the sake of a few additional pounds to their otherwise well-replenished coffers, is not merely a subject of surprise and regret, but merits the severest condemnation from every friend to public decency, morality, and health."

The parties who are the principal founders and proprietors of the numerous quack firms (self-dubbed consulting-surgeons) which infest this metropolis, are most of them (the author observes) more or less connected with each other by the ties of consanguinity or marriage. But as it is evident that it would interfere with their operations were they all to advertise under their real names, they each adopt some *nom de guerre*. "Thus they frequently assume the name of some eminent surgeon, and under the shield of this *clarum et venerabile nomen*, set up their priapian firm; and hence a name

which is associated with every idea of unsullied integrity and well-earned professional fame, is degraded into the service of a quack firm, and used for the purpose of levying black mail from the credulous."

There is another deception (the author observes) which they have artfully concocted in connexion with their advertisements, which is well calculated to deceive the ordinary class of patients. "I allude (he adds) to the numerous extracts of seemingly reviews of their works, which they append to their advertisements, and in which *parents, guardians, and patients* are all alike recommended to peruse the valuable remarks which are contained therein, on the 'diseases of which it so ably treats.'"

"The following is one of the modes which they practise in order to give an appearance of reality to these laudatory reviews. Having got an advertisement of the work drawn up, they procure some party to write an address, wherein their filthy book is recommended to the perusal of the different parties enumerated above. This address is annexed to the advertisement of the book, and its insertion duly paid for as an *ordinary advertisement*. After it has thus appeared in some newspaper, the whole, or some portion of it, is annexed to other advertisements, inserted in different newspapers, with the name of the paper in which it originally appeared as a paid advertisement, at the end; so as to create the belief that the quotation is a portion of a favourable review of the work by the editor of the paper, instead of being what it really is—viz., a portion of an address inserted and paid for as an advertisement by themselves."

The system of extortion and terrorism resorted to by these advertising firms is exemplified by a letter to the author from a person who had been so unfortunate as to fall into the hands of one of them, as well as by the remarks which follow it. "It is said (the author observes) that these scamps not only in the first instance adopt alternately every possible means of cajolery and intimidation, as shown in the preceding letter, in order to seduce patients into paying them large sums of money; but further, that all the letters the luckless patient, in foolish confidence in their honour and integrity, addresses to them, are religiously preserved, in order to serve as a further means of extortion and intimidation."

"Thus when at length the patient's faith in the realization of their promises of a cure is exhausted, and probably all his available pecuniary means also, and he is in consequence desirous of withdrawing himself from their coils, he is at once informed that they cannot think of allowing him to do so until he is cured. Should he persist in his determination, he is met with the threat, that if he does not continue the treatment, his *friends* will be informed of his condition, and copies of his letters furnished to them. Now, when it is known that most likely these letters contain admissions of criminal indulgences in the practice of self-abuse, and most exaggerated descriptions of the patient's state of debility therefrom, and perhaps even statements of utter impotency, it will be at once seen what a terrific and powerful engine of extortion these threats become. Need we, then, wonder that every possible means is adopted to raise the means of satisfying these almost insatiable wretches, particularly when they promise to return the victim's letters on their demands being paid. . . . A respectable surgeon informed me that he knew an instance in which a clergyman had been cheated by one of these pseudo-surgeons out of acceptances to the amount of a thousand pounds."

We have delayed so long upon the contents of the preliminary chapter, that we have scarcely left ourselves space for any notice of the subject specially treated of by Dr. Pickford; but the moderate price at which the *brochure*, we presume, is sold, places it within the reach of every one interested in the matter; and we shall conclude with the following extract from the author's concluding remarks on the treatment of spermatorrhœa:—

"According to the preceding investigations, imperceptible losses of semen may stand to the general condition of the patient in the three following relations:

1. They occur in healthy persons.
2. They occur in diseased persons, but are rather the con-

sequence than the cause of the malady, and are of no further consequence.

3. They are the cause of the disease.

To the two first classes, the cure of these imperceptible emissions would do no good; healthy persons may make themselves perfectly easy about the matter; and hypochondriacs who suffer from imperceptible seminal discharges, must be treated in the same manner as other hypochondriacs. And similarly, spinal irritation occasioned by this so-called spermatorrhœa, requires no other treatment than irritation without it. To this class belong the great majority of the diseases which Lallemand and his followers attribute to spermatorrhœa. Fortunately for humanity, true spermatorrhœa is, as Pauli justly observed, an uncommon disease."

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, APRIL 28, 1852.

### IRISH BARDS AND SCOTCH REVIEWERS.

A NORTH British contemporary of ours affects to be hugely astounded, if not indignant, because that we, on the 17th of March last, of all days in the year, contumaciously insinuated that an author of the present times might possibly fail to acknowledge his obligations to preceding writers; and still worse, that we had the temerity to hint that even a conscientious contributor north of the Tweed might inadvertently do so. Anything to the contrary notwithstanding, we must, nevertheless, adhere to this our imprudent expression of belief; convinced that every shrewd reader (our contemporary not excepted) is of the same opinion. We confess that the reason we assigned for the commission of this sin in the locality indicated was not, perhaps, so flattering as the indigenous of it might have expected, and therefore are we bound to retract. We hastily hinted that in that part of the world, a knowledge of what was passing in the rest might be limited by a want of information arising from a prudent disinclination to pay for it in the shape of books; but we now see that we were wrong, for we find that our northern neighbours, so far from being parsimonious in this respect, are quite prodigal. We have made inquiry, in fact, and find that the demand for medical books and journals amongst them is so great that the London booksellers can scarcely supply it. In order to remove all doubts, however, as to our estimate of the character of our thrifty old friends, we once for all declare that we believe them to be the most moral, religious, sober, learned, brave, eloquent, poetical, critical, and wise people on the face of the earth; and, moreover, we admit that plaids are better than pea-jackets, and kilts than trowsers; that oaten cakes are preferable to wheaten-bread; and "Finden haddies" to juicy mutton chops! What more can they ask? But we fear that there is something at bottom which provokes the display of crusty feeling to which we allude, some "nursing of wrath to keep it warm," of which we should not be the victims. If the shopkeeping "patrons" of the Edinburgh University have, with their seven clerical allies in Dublin, brought "Medical Degrees" to a discount by their stupid greediness, why should we be expected to answer for such blundering. Be this, however, as it may, we must still adhere, as we have said, to the opinion we expressed respecting the prevalent practice of palming off as something original or novel what has already been well considered. It matters little whether this be done from ignorance or design, the mischief is the same: the sources of knowledge are obscured, and its archives are rendered of doubtful authority. In the article which stirred up the bile of our brother editor, we advisedly alluded to the

"happy state of ignorance" which is displayed in the "original communications" of certain contributors to certain journals. Does he mean to deny that such a display is not made, or that such a result was not inevitable, seeing the vast undigested heap of materials which a writer has before him? When this ignorance or negligence is displayed in mere ephemeral essays, or in the recording of facts to be added to the common stock, we have no right to complain; but when men undertake researches or inquiries to solve disputed questions, or set up claims to discoveries, they should neither reject nor suppress; and above all things, they should not from unworthy motives conceal the truth. The Scotch journalist to whom we have been alluding affects to believe that in these observations of ours we complained of the "want of originality displayed in modern medical journalism," but he well knows we complained of no such thing. We complained of the dishonest suppression of the truth as to the labours of others to enhance claims to originality. He twits us, too, with our want of what he doubtless prides himself on, the much-prized "original communications" of journalism; but our readers probably prefer a selection made from the heap rather than a portion indiscriminately administered. If the MEDICAL PRESS was stuffed with these same "original articles" (and truly very original some of them are), we suspect our subscribers would soon feel the effect. The truth is, that what we are here taunted with is just what we take credit for. Ours is not a farrago of egotistical effusions or tedious repetitions of notorious facts and arguments, but the best selection we can make of what is of practical value. We aim at making our readers acquainted with what is "going on in the medical world," rather than ministering to the vanity of what are facetiously called "authors." As to our liberal selection from the pages of the *Edinburgh University Journal*, we were not before aware that we erred in that way, and we shall endeavour to avoid the practice in future. Whether our contemporary's contributors will be the better of that remains to be told.

### REMUNERATION FOR PUBLIC MEDICAL SERVICES.

THE following pertinent communication records another example of an old and crying grievance, which is absolutely intolerable. Over and over again promises were given by "the authorities" that provision should be made to prevent such dishonest extortion, but they have been all broken. That W. F. WINSLOW, S.I., is liable for the attendance and treatment there can be no doubt, and however disagreeable it might be to do so, a call on him for payment might settle the matter. The "Board of Health" is an ancient institution in Dublin Castle, having no other power in such cases than the allocation of some small fund to this contrivance for "doing the doctors:"—

#### TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—Can you inform me who constitute the Board of Health, and what rule do they follow in deciding on the value of medical services?

On the night of the 9th of last February, I was waited on, after ten o'clock, by one of our city constabulary, with an urgent representation that a crown witness in his charge had been taken suddenly and alarmingly ill, that her life was of importance to the ends of justice, as she was the principal witness in a crown prosecution to come on at the assizes early in the ensuing March, and that medical assistance was promptly required.

The following is a copy of a note which I also received from his officer:—

"SIR,—You will have the goodness to attend a crown wit-

ness in charge of Acting Constable Jordan, until out of danger, and who I understand is very unwell.

W. F. WINSLOW, S.I."

This note was sent me on the following day as a guarantee for my attendance. The haste and urgency of the case was such as not to allow of the constable's procuring it on the preceding night when I was first called on, and when I was induced to attend by very urgent representations, which were fully justified by the facts of the case. Under these circumstances, I attended at once, and continued in attendance till the 24th of February. I then filled up the usual printed form, and forwarded it with my solemn attestation annexed, to the truth of the following particulars:—

That I am a duly qualified surgeon.

That I had paid at least eight visits between the 9th and the 24th of February, inclusive.

That my attendance was unavoidably prolonged by a relapse brought on by an indiscretion of diet.

That my first visit was paid after ten o'clock at night.

That I was induced to attend by the pressing representations made to me; and, finally, I gave a list of the medicines employed, which was sufficient in itself to show that decided measures were necessary, and (without the collateral evidence already alluded to) that the case was one of some consequence.

After waiting now until the end of March, I receive from the Crown Solicitor's office a post-office order, with the usual intimation that it was the amount awarded me by the Board of Health in the case referred to. The order was for £1 !!

Allow me, sir, to analyze the duties for which the Board of Health pronounce this to be an equivalent:—

One night visit	...	...
Seven subsequent visits	...	...
Medicines as certified	...	...
Writing sundry prescriptions	...	...
Apothecary's bill	...	...
Filling a printed form of affirmation with particulars	...	...
Seeking out a magistrate and making a solemn affirmation before him	...	...

£1 0 0

Out of this sum I have to pay an apothecary.

The printed form, as known to those acquainted with it, is sufficiently lengthy and precise. The particulars were, I may say, sworn to.

I do not think the above award can be considered a just one, and I think it would be fair that the profession should know who the Board of Health are, and also by what considerations they are influenced in the adjusting their awards?

Had I contemplated such a result as the above, I need scarcely say I would not have undertaken the case on any account. I attended on the supposed good faith of a Board who I knew would be put in full possession of all the particulars of the case.

It is vain to plead a sense of public duty as the motive for making this award. Public duty neither sanctions nor requires either injustice or oppression. After services have been extorted by pressing solicitations, and yielded on supposed good faith, is it consistent with any acknowledged principle of right to take an unfair advantage and unduly disparage them, when they can be no longer refused or retracted?

As I do not know who the Board of Health are, I cannot intend anything individually personal. I have had good reason on several occasions to complain of their awards, but knew there was nothing to be gained by remonstrance. I am a Fellow of the Royal College of Surgeons, Ireland, and Surgeon to a leading provincial hospital. I am now some sixteen years in the public service. I have never, either as a student or practitioner, disgraced myself or my profession. It cannot be on the score of want of character or qualification that I am denied reasonable remuneration.

It would be fair, I repeat, that the profession should be made acquainted with the names of those from whose hands they have to expect such treatment, and fair that they should know what considerations regulate the degrees of disparagement to which they are liable, in order that they might know when to decline the honours of the public service.

I am aware, sir, how useless it is to complain of outrage or injury in the medical profession, and I know that mine is not by any means an extreme case. The periodicals from day to day publish cases of legalised injustice which dare not be practised on any other body, but which seem to be regarded with most inconceivable apathy and indifference by

the body themselves. Witness the extraordinary case of hardship, related in No. 677 of the MEDICAL PRESS, sustained by Dr. Hans Fleming of Carrickmacross, but which appears to have excited not so much as the attention of the profession. When I regard it, and the many other similar cases of almost daily, but unheeded, occurrence, I cannot expect that my case will excite any interest. I publish it from a sense that it is some sort of duty to the profession to put those things on record, and also to prevent an indignant silence being misconstrued into acquiescence.—I am, sir, your obedient servant,

ZACH. JOHNSON, F. and L.R.C.S.I., &c. &c. &c.  
Kilkenny, April 22, 1852.

#### UNIVERSITY REFORM AND MEDICAL INTERESTS.

WE wish the Graduates of the London University every success in their endeavours to assert their rights to a legitimate academic position, if for no other reason for this, that it may stir up the Graduates of the other Universities to do the same. It is high time for those of Trinity College, Dublin, to look after their distinctions and privileges, purchased as they have been at an exorbitant price, and threatened as they are with deterioration by most questionable contrivances to facilitate graduation with a view to financial benefits, rather than educational improvements. Here is an extract on the subject:—

Since we last adverted to the present defective constitution of the University of London, and the organization of the graduates to obtain that position which is their due, the committee whom they had entrusted with the advocacy of their cause have prosecuted their demands with a temperate vigour which deserves success, and, we will add, with an ability which will assuredly achieve it. Up to this period of last year, the fruit of three years' active operations may be expressed as an admission on the part of the senate and Sir George Grey, the then Secretary of State, that the claim of the graduates to a place within the pale of the University-Constitution was, in principle, just one; but the admission was minimized by the qualification, that in the opinion of the senate, the time for such a readjustment of the university had not arrived. The graduates have done wisely in accepting the admission, and repudiating the qualification. They had regard to their numbers, which already surpassed the minimum indicated by the senate itself; they considered that the very degrees they had obtained from the university were a proof of their fitness to exercise some share in its government; they felt that men who in honourable competition in the world had earned for themselves prominent positions and important trusts in almost all the foremost educational institutions in the kingdom, could not be unworthy of a recognized position in their own university. But so long as the principle only is admitted, little real advantage is gained. The demands of the most undeniable expediency and justice are baffled by a temporizing policy. If the graduates be convinced that they have a just cause, let them not for one moment relax their exertions, nor be entrapped into inaction on the faith of a promise, the fulfilment of which may, unless they bestir themselves, be indefinitely postponed. Success, whenever it comes, will depend upon themselves. That the graduates' committee are animated by this conviction, they have given us the most satisfactory evidence in their recent proceedings. The senate have so far abandoned the cunctatory plea, as to refer the question of the graduates to a select committee. It is, therefore, again under their consideration; and it is not unreasonable to conclude that it is at last ripe for discussion. Lord John Russell has expressed his approval of the general movement, and he has not hinted that the time is inopportune. Sir James Graham, whose accession to the senate was an assurance that a liberal policy would be pursued, has publicly, before a meeting of the proprietors of University College, given his sanction to the movement; and he has added a phrase of encouragement to the graduates, which we would exhort them to adopt as their watchword. Referring to the past proceedings of the graduates, he reminded them that "a step once gained was never lost." A great step has been gained. It remains for the graduates to improve upon their position—not to tarry upon that step, but to make it the means of gaining another and yet another, until the last, the crowning one of all, is surmounted. That veteran reformer, Mr. Hume, has also

added the weight of his experience in support of the graduates. But not only have individuals expressed their approbation; nearly twenty of the most influential and considerable of the affiliated colleges have responded to the appeal of the committee, and have either directly memorialized in favour of the graduates' movement, or have by resolution or letter recorded their adhesion. The graduates have thus acquired a large amount of external support in advancement of their claims. It is, indeed, in every point of view a public question, and in the time of need the public influence will not be wanting. But at the present juncture, the graduates must continue to rely upon themselves. To justify in the public mind the two great measures of university reform—Incorporation of the Graduates and Parliamentary Representation—the graduates, who will be the immediate recipients of a great public trust, and which they will be expected to exercise in the promotion of free education, must prove themselves to be not unworthy of the office. To do this, they must show that they have faith in their cause and confidence in themselves. By the precedent of the ancient universities—by the expressed resolutions of the senate—by the approbation of powerful statesmen—by the support of numerous important public bodies—by their own scientific and social position—the graduates are, by every plea of right and expediency, entitled to what they demand. Let them demand it boldly, if need be, from the legislature itself, and they will not long demand it in vain.—*Lancet*.

#### THE ENGLISH COLLEGE OF SURGEONS AND THE HOMŒOPATHS.

FROM the following we learn that Members of the London College may globulize gulls with impunity, and wherefore should they not, for they have ample warrant to deal with them more substantially. We see no reason in the world why out-and-out Doctor-Apothecaries, or Apothecaries'-Doctors either, should enjoy a monopoly. The two crafts, homœopathy and allopathy, are fairly pitted against each other, and convinced are we that honest and judicious practitioners and their patients will be the better of it in the sequel:—

The Council of the College of Surgeons have sent the following reply to the memorial of the meeting of the medical men of Hull and its neighbourhood, praying them to express some opinion on the doctrine and practice of homœopathy:—

“College of Surgeons, March 9, 1852.

SIR,—I am desired to acquaint you that your communication, enclosing copies of resolutions of a meeting of the medical profession of Hull and its neighbourhood, held in the Hull General Infirmary on the 6th of January last, on the subject of homœopathy, has been laid before the Council of this College, and that the Council, after mature deliberation, consider it inexpedient to interfere in the matter.—I have the honour to be, &c.,

EDM. BALFOUR, Secretary.”

#### THE TITLE OF DOCTOR.

WE feel very much inclined to agree with the writer of the following note as to the true nature of the public acceptance of the title “Doctor.” Whatever may have been its early origin, it is clear that it is now universally used in the “vernacular,” to designate proficient in the healing art, be their pretensions what they may. It is the title of the *order*, of which Physician and Surgeon are the *genera*, including many *species*, and these again some very curious *varieties*. Why, being thus a name, common to all candidates for employment in the curing trade, it should be coveted by men of higher aim we cannot tell, for assuredly it has lost its efficacy as a distinction. In Dublin it is probably owing to the old trick of the Doctors and Apothecaries to exclude Surgeons from medical practice, on the plea of exclusive devotion to surgical manipulations; but as this “dodge” has become stale, it seems strange that men looking to surgical station will still peril their characters by the adoption of the title. Those who have been so unlucky as to have acquired the title cannot now get rid of

it, but let the rising generation consider its effect in good time. Doctor would look very queer before the names of POTT, HEY, COOPER, ABERNETHY, BRODIE, and others:—

SIR,—I would suggest to you, not to be so exclusive about the use of the title—“doctor.” It is a convenient title for the medical attendant, and I see no reason why physicians should have a monopoly of it. The people always will say “our doctor,” whether “their doctor” be physician, surgeon, or apothecary, and I think the medical attendant should have the privilege of styling himself by the title the people ordinarily give him, whatever his grade may be. But then, again, as you are going to have only one scale of education for all medical men, this distinction about title is the less tenable in your scheme. Some may, having passed the examination, join the College of Physicians, and some the College of Surgeons, whilst others will remain general practitioners; but if they are to be educated alike this invidious distinction of title would be unjust. Let them all be “doctors,” for “doctor” is the title the public will give them; and to keep it from being a “nickname,” let it be their rightful title. But it is intended that those who may select to join the Colleges of Physicians and Surgeons respectively, shall have to undergo another examination; if so, your medical reform will make little or no change beyond a superseding of the Apothecaries' Hall in its functions of examining and giving a licence to practise. All those under the new law who shall not have joined the colleges, will be looked upon as mere apothecaries under some other title—a title it appears not yet settled on, but that title, as the act, or rather proposed act implies, must not be “doctor.” Nor can it be surgeon, for the using of that title would be a usurpation, without the diploma of the college. When I was young there was a medical practitioner who kept a shop in a certain city, and he had on the door his name, with surgeon-apothecary and midwife after it. It so happened that he was a good-looking fellow, and that a wealthy heiress fell in love with him, and married him. He took her name, and having moved into a neighbouring square, put it on his door after his own name, but no surgeon-apothecary or midwife. His own name was Davis, the wife's maiden name, which he adopted, was Issadore, rather an uncommon name no doubt, and many of his patients seeing that the former titles were no longer on his door, came to the conclusion that Issadore was a new technical word, meaning surgeon, apothecary, and midwife altogether. It is, I submit, just such a word we want as a title for the new-fangled practitioners, if the use of the title of doctor is to be prohibited. But I am for the good old title of doctor; it means all, and it is short and handy, and every one has it by heart, and will apply it to the medical attendant in spite of all the penal laws you can enact.—*Extract from letter in Provincial Journal*.

#### CORRESPONDENCE.

#### OPERATION OF THE DISPENSARY ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—In the leading article in your impression of Wednesday, the 14th inst., in reference to the operation of the new dispensary act, you very fairly state, and I quite agree with you, that “the existing critical state of affairs calls for a very prudent exercise of your editorial functions, and a very careful consideration of the policy which results may suggest;” but after relating one case of great hardship, out of the very many which have occurred to the members of the medical profession in carrying into effect this new law, you go on to state—“It is vain to deny that much dissatisfaction prevails as to its defects in working properties, and that loud complaints are made against those entrusted with its execution, on account of some of the results of its operation, but it is impossible now to call for its abrogation; it is also obvious that an inclination prevails to attribute the defects in its operation to a want of decision on the part of one more than another of those entrusted with its execution, but this view we cannot take.” Now, sir, permit me to say, the majority of the medical men through Ireland have mainly themselves to blame for many of the evils they now complain of. If the members of the medical profession in Ireland were more unanimous in purpose, and less selfish, and work together more for their common cause, they are a body quite important enough; and, by unanimity, possessing sufficient influence to protect the just rights of the profession to which they belong; and by adopting such a course of action, place

those in power in a position to assist them, but their motto seems to be "every one for himself." A general meeting of medical men was convened in Dublin in January last to adopt measures to forward and protect the interests of the profession. How was it attended? Few came, and many had not even the courtesy to send an apology for their absence. From that meeting, over which Dr. Kingsley of Roscrea—a vigilant and indefatigable friend of the profession—presided, the following resolution was adopted, and most extensively circulated—viz.: "That the secretary be directed to apply to the medical attendants of dispensaries and hospitals for a further subscription of 10s. each for the purpose of paying a balance which remains due to their late honorary secretary, Dr. Knox, as their agent in London, and for defraying the expenses that must necessarily be incurred in endeavouring to procure further legislation, and for adopting such ulterior measures as may be required to promote the interests of the medical profession." Now, sir, I ask, where the interests of the profession were so much concerned, how has this appeal for the paltry sum of 10s. been responded to? I regret to say by scarcely a reply. With such a state of apathy, indifference, and selfishness, so generally existing amongst the ranks of the medical profession in Ireland, how is it to be wondered at that the interests of that profession should be neglected, and its members ill-used, particularly when we recollect that in carrying the new dispensary act into operation, we are placed so much in the hands of parties who, generally speaking, pit the doctors *versus* the ratepayers, and being all of the latter class themselves, decide, as a matter of course, in their own favour? I think, however, the lesson which dispensary medical attendants throughout Ireland have now received, must open their eyes to their present critical position; and that if even now they could be induced to come forward generally, not for the purpose of factious opposition—such a course would be most injurious—but to consult by what means their present grievances could most effectually be brought under the consideration of the proper authorities, a beneficial result would follow.—I remain, dear sir, yours very truly,

HENRY I. SMITH.  
Mountrath, 2, Coote Terrace, April 16, 1852.

#### TO THE SURGEONS OF DISPENSARIES.

GENTLEMEN,—I would address myself particularly to you whose dispensary year ended on the 1st of December. Are you willing to lose the subsequent three months' pay without an effort or remonstrance? What would you think of forming a committee, collecting funds, taking advice, and making some general and combined movement? A memorial to the Lord Lieutenant, or to the Commissioners, or a petition to the House of Commons? I need not tell you it would be useless to make any application to the boards of guardians.—I have the honour to be, gentlemen, your obedient servant,

ONE OF THE SUFFERERS.

April 26, 1852.

#### INSURANCE COMPANIES.

##### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—As I consider you are conferring a benefit on our profession by exposing the names of those insurance offices that expect confidential professional information gratis, I beg to mention that "The Clerical, Medical, and General Life Assurance Society," No. 99, Great Russell-street, Bloomsbury, London, and 18, Hardwicke-street, Dublin, according to their agent's letter at present before me, "never pay a fee to the referee of the party assuring." I am not aware what claim it has to be called "Medical," or to receive support from that profession. Should you think this worth inserting, by doing so you would oblige yours,

JOSEPH ROBINSON, M.D., &c.

Ballibay, April 22, 1852.

TO CORRESPONDENTS.—The abstract of the proceedings of the Cork Medical Society in our next.

#### UNIVERSITY OF ABERDEEN.

THE following gentlemen have passed as graduates of M.D. of University and King's College, Aberdeen, on the 15th instant:—Ernest Elliott, Portsmouth; George Crosland, Yorkshire; Robert Molloy, Pentonville; William Horne Popham, London; Owen Richards, Cardiganshire; Philip Brown, Durham; John D. Jones, London; James William Young, Co. Meath; James Ross, Elgin, N.B.; Christopher Antisell Allen, Cork.

#### MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE Treasurer thankfully acknowledges the receipt of the following sums in aid of the Fund:—

F. L'Estrange, additional donation	...	£5 0 0
Dr. Mollan, Dublin, subscription	...	5 0 0
Dr. Andrew Nolan, Wicklow	...	1 1 0
Dr. Harvey, Dublin, do.	...	1 1 0
Dr. J. F. Duncan, Dublin, do.	...	1 1 0
Dr. Hill, Dublin, ...	...	1 0 0
Dr. Quin, Dungarvan, do.	...	1 1 0
Dr. Christian, Dungarvan, do.	...	1 1 0
Dr. Duncan, sen., Finglas, do.	...	1 1 0
Dr. J. Wilkinson, Limerick, do.	...	1 0 0
Dr. Lynch, Loughrea, do.	...	1 0 0
Dr. Babbington, Coleraine	...	1 1 0
Sir Alan Bellingham, Bart., Castlebellingham	...	1 1 0
Dr. McMunn, Sligo	...	1 0 0

Subscribers are earnestly requested to send in their subscriptions with as little delay as possible. The annual distribution of the Fund will take place on the first Monday in June, but the sums to be awarded to the applicants will depend upon the amount transmitted to the Treasurer previous to the closing of the year's account.

JAMES F. DUNCAN, Treasurer, *pro tem.*

19, Gardiner's-place, April 26, 1852.

M. W. HANLON, M.B.

SEA-SALT IN DRUNKENNESS.—In one of the last numbers of *L'Abeille Médicale*, M. Laloux publishes a paper on the utility of injections of sea-salt to dissipate rapidly the symptoms of the severest cases of drunkenness. The solution which M. Laloux injects into the intestine is composed of two large spoonfuls of common salt dissolved in four glasses of tepid water. There follows a considerable evacuation, in consequence of which all the functions resume their office. This remedy has the advantage over ether and ammonia in being procurable everywhere; and we had an opportunity of observing, in an analogous case, that it was more powerful than ammonia in putting a stop to the coma which follows alcoholic intoxication.—*Jour. de Méd.*

**SCHOOL OF SURGERY.****ROYAL COLLEGE OF SURGEONS IN IRELAND.**

THE Summer Courses of Lectures commenced on Monday, the 26th of April, when Lectures on the following subjects were delivered, in accordance with the regulation of the Council of the College:—

Materia Medica	...	...	Dr. Williams.
Medical Jurisprudence	...	...	Dr. Geoghegan.
Practical Chemistry	...	...	Dr. Barker.
Botany	...	...	Dr. A. Mitchell.

Examinations will be held, and Premiums awarded to the successful Candidates, at the termination of the Session.

**CITY OF DUBLIN HOSPITAL.****SUMMER SESSION.**

THE Clinical Lectures and other forms of Instruction commenced in this Hospital on the 26th of April. By a recent Ordinance of the College of Surgeons, separate Certificates of Hospital Attendance, during the SUMMER SESSION, are required.

**DISEASES OF THE EYE.****SUMMER SESSION.**

*DOCTOR JACOB* will commence his Lectures on DISEASES of the EYE, in the City of Dublin Hospital, on Monday, the 10th of May, and will continue them during the SUMMER SESSION, so as to form a complete Course of OPHTHALMIC SURGERY.

**SURGICAL SOCIETY OF IRELAND.**

THE last Meeting of the Society for the Session 1851–52, will be held at the Royal College of Surgeons on Saturday evening, May 1st, at half-past Eight o'clock.

The President of the College will take the chair.

By order,

CHARLES BENSON, } Secretaries.  
O'B. BELLINGHAM, }

April 22, 1852.

**MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.**

THE Annual Distribution of the Funds at the disposal of the Society will take place on the first Monday in June.

Applications for assistance must be made by printed forms, to be obtained from the Honorary Secretaries, and must be sent in to the Branch Associations before the 6th of May, or to the Parent Society before the 10th of May.

Branches are established in the principal towns of Ireland, and with Honorary Secretaries, as follows:—

Armagh, Dr. Colvan; Belfast, Dr. Stewart; Cork, Dr. Lloyd; Newry, Dr. Erskine; Waterford, Dr. Carroll.

The applications are to be forwarded to the Secretary of the nearest Branch, if any be near, or to the Secretaries of the Parent Society in Dublin.

Subscribers to the Parent Society are requested to send in their contributions as soon as possible to the Treasurer, Dr. Duncan, 19, Gardiner's-place, Dublin; and subscribers to the Branch Associations, to the Local Treasurers respectively.

By Order,

WM. KINGSLEY,

CHAS. BENSON,

Hon. Secs. Parent Society.

Royal College of Surgeons, Dublin, April, 1852.

**NEW ROSS UNION.****Carrigbyrne Dispensary District.**

THE Committee appointed for the above District will, on Tuesday, the 4th of May next, at the hour of twelve o'clock (noon), at the Carrigbyrne Dispensary Board-room, proceed to elect

**A MEDICAL OFFICER**

for the above District. He must be duly qualified as required by the rules and regulations of the Poor-law Commissioners, must reside within the District, and compound and dispense the required Medicine. The salary is fixed at £90 per annum.

Sealed applications, containing testimonials as to competency and character, will be received by the Chairman of the Dispensary Committee, directed to S. D. Goff, Esq., Hore-town House, Foulk's Mill, New Ross, on and up to Monday, May 3rd.

The personal attendance of applicants at the time of election will be necessary.

Carrigbyrne Dispensary Board-room, April 13, 1852.

**SCHOOL OF PHYSIC IN IRELAND.**

THE following Courses of Lectures will be delivered during the Summer Session in the Medical Lecture Rooms of the University:—

Practical Chemistry...	Dr. Apjohn,	11 to 12 o'clock.
Botany ... ..	Dr. Allman,	3 to 4 o'clock.
Medical Jurisprudence—	Dr. Brady,	4 to 5 o'clock.

Fee for each Course, Three Guineas.

WM. EDWARD STEELE, M.B.,

Fellow and Registrar, King and Queen's College of Physicians.

**THE ROYAL MEDICAL HALL,**

64, DAME-STREET, DUBLIN.

 Change of Proprietorship.

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a legitimate and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

\* \* GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

**THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

### SURGICAL SOCIETY OF IRELAND.—APRIL 3.

Mr. TRANT, President of the College, in the chair.

#### ON SUDDEN DEATH IN THE PUERPERAL STATE.

By ALFRED H. MCCLINTOCK, M.D., F.R.C.S.I.,  
Ex-Assistant of the Dublin Lying-in Hospital.

In a former communication which I had the honour of reading before this Society,\* I treated of sudden death met with in the puerperal month, from idiopathic asphyxia, from syncope, from the shock of parturition, from mental impressions, and from the admission of air into the great vascular canals through the uterine veins. In the course of the discussion which ensued upon the reading of that paper, I ventured to suggest, relative to the cause of death last mentioned, that before we could regard the simple presence of air in the heart and vena cava, as proving that it had entered through the uterine veins and destroyed life, we should know whether air was ever found in the same situation without having contributed to the patient's death. I was not then myself aware of any such observation having been made; but Dr. Henry Kennedy, in the course of some remarks which fell from him, alluded to cases where he had seen air in the heart and cavæ, without its having had any appreciable connexion with the cause of the patient's decease. Devergie also has noticed the extrication of gas within the arteries and veins as a product of incipient putrefaction; furthermore, Ollivier (d'Angers) in the *Archives Générales de Médecine* for January, 1838, expresses his belief that life is sometimes extinguished in a manner almost instantaneous from the generation of gas in the circulating fluid, and its accumulation in the right chambers of the heart. To sustain this opinion he brings forward three cases, having no connexion whatever, be it remarked, with childbed. Quite recently a paper was read by M. Durand Fardel on this subject before the Academy of Medicine of Paris, and in it is related a very remarkable case where sudden death seemed to have been produced by

the extrication of gas within the vascular canals, for not only was air found in the heart, cavæ, and abdominal venous system generally, but—and this deserves particular attention—at the moment of dissolution its presence was manifest in the blood which flowed freely from a vein in the arm, thus proving that it was not a merely post-mortem occurrence. To give the full details of this case here would take up too much time. They are to be found, however, in the *MEDICAL PRESS* for March 17, 1852.

Now, the above facts, if they do not directly militate against the supposition of death having resulted in the cases quoted by Dr. Cormack, from the introduction of air into the uterine veins, at all events tend to depreciate the value of the evidence on which this assumption rests. The safest and most cautious conclusion, therefore, at which to arrive in the present state of our knowledge touching this pathological question, would be this, I think: that the simple presence of air in the heart of a puerperal patient cannot *per se* be regarded as adequate proof of its having entered through the uterine veins and proved fatal, since there is ample evidence to show that the same post-mortem appearance may be met with in persons in whom there was no reason to have suspected the existence of gaseous fluid in the heart or great vessels.

The causes remaining to be described which may, amongst newly-delivered women, abruptly bring the functions of life to a stand, are very various, and I cannot pretend to describe them all. To do so would require very extended and careful research through the records of a department of medicine remarkable for the zeal and diligence of its cultivators.

Dr. Meigs of Philadelphia seems to be the first who announced the opinion, that a woman who has sustained much loss of blood during labour is liable for some days afterwards to the formation of a coagulum in the heart, should fainting take place from any cause. His explanation of this occurrence is best conveyed in his own words:—"It is well known that the coagulability of the blood is greater in proportion as any hæmorrhage progresses—therefore a woman who has lost during her labour forty or eighty

\* *MEDICAL PRESS* for March 10, 1852.

ounces of blood, has the rest of it more coagulable than it was before the flooding commenced. Again, fainting consists in the too little intensity of the presence of the blood in the brain; and a woman just gone through a flooding, experiences a sensation of faintness from lessened vascular distension of her encephalon. If she suddenly assume an erect position, the tension becomes instantly lessened in consequence of the gravitation of the blood. But—and this is the danger—if she faint badly while her blood is become thin and highly coagulable from hæmorrhage, the scarcely moving current partially stops in the heart, and when she comes out of the deliquium, if ever, she does so with a coagulum in the auricle and ventricle; she has got a false polypus in the cavities, and she will surely die.” Death from syncope is doubtless what should be most apprehended where a woman who has had immoderate uterine hæmorrhage faints. In the passage above quoted, Dr. Meigs points out another and no less formidable source of danger, and he substantiates his views by two cases in which he diagnosed this lesion during life, and the examination of the bodies after death made manifest the truth of his opinion. In these instances death could not be said to have been unexpected or sudden; but that it may, to a certain extent, be so, is shown by a case which was communicated to the Edinburgh Obstetric Society by Dr. Keith. In November, 1850, this gentleman delivered a lady of twins at her first confinement. The labour was tedious, and she was kept under the influence of chloroform for thirteen hours. The first child was extracted with the forceps, and the second presented footling. With the expulsion of the placenta, an enormous quantity of blood escaped, but the uterus contracting immediately arrested all further discharge. “The effect of the sudden loss of blood was such that for a few minutes the pulse could not be felt at the wrist at all. The patient was still under chloroform, but for a short time she seemed in a state of syncope. This very soon passed off; the pulse returned to the wrist; she slept for a short time quietly, and on awakening showed no unusual symptom. From this time up to the fifth day, she seemed to be making a fair enough recovery, if we consider the severity of the labour and the quantity of blood lost. The discharge was natural; milk appeared in the breasts, though in small quantity; she took her food well; and with the exception of an acute pain, apparently of a neuralgic character in the lower part of the back, for a few hours on the second day, she made no complaint of pain or even of tenderness anywhere. During this whole period, however, there was an unusual degree of restlessness, and an undefined feeling of discomfort, for which, though frequently asked, she could give no definite cause. The pulse was also faster than usual, and very small. These symptoms I ascribed to a naturally irritable and excitable temperament, aggravated by the shock of the labour, and the loss of blood, and partly to the heart’s action being deranged by an unusual degree of flatulency, from a disordered state of the stomach and bowels. On the morning of the fifth day the nurse told me she had spent a good night, and her own principal request was, that she might have a partridge for dinner. On feeling the pulse, however, it was much more rapid than on the previous day, and very feeble. As I could discover no other cause for this, I supposed she had been excited by the effort of nursing the child—an office which appeared to annoy her very much, and with which she would willingly have dispensed. I, however, told the nurse, who had not the slightest apprehension of any mischief, the state of the pulse, and asked her to send for me immediately if she saw any unfavourable symptoms. I left at ten o’clock and at twelve an urgent message was sent to my house. As I was out at the moment, Dr. Duncan was sent for, and at half-past twelve he found her pulseless, and evidently sinking. I saw her half an hour later; she seemed then to have very slightly revived, after taking a large quantity of champagne and brandy. The pulse was, however, quite gone at the wrist, the heart’s action extremely rapid and feeble, the breathing very laborious. She was still per-

fectly sensible, and could speak without difficulty, and the extremities retained their usual warmth. Dr. Duncan suggested the presence of a clot in the heart as the cause of the symptoms—an opinion which I at once adopted as giving the only satisfactory explanation of the sudden sinking. Dr. Simpson saw her at half-past two o’clock. She died at three o’clock. The body was examined twenty-four hours after death, in the presence of Dr. Simpson, Dr. Duncan, and myself. On opening the abdomen, a large quantity of serum was found in the cavity of the peritoneum, and a very thin layer of very soft lymph covered some portions of the intestines. This was most unexpected to myself, as I had entertained no suspicion whatever of the existence of peritonitis in even the slightest degree. The uterus showed no marks of inflammation, and was in all respects such as a healthy uterus would be at the same period after delivery. As the condition of the abdominal cavity appeared thus to show a sufficient cause for death, our expectation of finding a clot in the heart became less sanguine; but on exposing that organ, we found the right side unusually distended, and on opening it, the right auricle was found quite filled with a large mass of fibrine, quite colourless, and especially, at one part where it adhered to the wall of the auricle, of a firm and leathery consistency. It appeared altogether different from the clot which is often found in the heart after a lingering death. I am inclined to believe that the serous effusion into the peritoneum was in a great measure the result of the mechanical obstruction to the return of the blood to the heart.” Dr. Duncan described the symptoms of this patient when he saw her as “distinctly those of asphyxia modified. There was the dinginess of skin, blackness of lips, with great respiratory distress, and at the same time apparent freedom of the act of respiration.” These symptoms, he thought, were connected with the unusual clot found in the heart after death.

I have thought it right to cite this case, though I am aware it is open to controversy, from the circumstance of peritonitis having been present. Still I cannot, with Dr. Simpson, simply consider it “as one of common puerperal peritonitis in which the symptoms had been more masked than usual.”

On the whole, then, it is but fair to say that the evidence in favour of “heart clot” (to use Dr. Meigs’ term) being a cause of RAPID death after delivery, is as yet rather deficient, but that the possibility of its occurrence may be admitted. Somewhat allied to this lesion is the one about to be described—namely, obstructions of the pulmonary artery, a subject to which Mr. Paget, I believe, was the first to draw the attention of medical men in these countries. His researches on this disease show “that the obstruction of a large and quickly increasing portion of the pulmonary circulation, if it be not complicated by other disease, is usually unattended by disturbance of the respiration or any other important function.” He has also stated—and this is more to our present purpose—that of the patients whose cases had been recorded at the time he wrote, and which were then fifteen in number, seven had died suddenly. Towards the conclusion of his second paper on this subject, he has offered the suggestion, “that many cases of sudden death, for which no cause has been found, or which have been ascribed to some insufficient or improbable cause, have depended on clots obstructing the pulmonary arteries; and that clots of the same kind, which are often found in the systemic veins, and are usually ascribed to phlebitis, though the coats of the vein are healthy, are the consequence of stoppage of the blood similar to that which he has described, and from a similar cause,”—that cause being an alteration in the composition of the vital fluid. Now, without following Mr. Paget in his reasoning upon the etiology of this disease—although such would lead us to infer that the state of pregnancy rather favoured its development—I shall simply narrate an example of sudden death from this cause twelve days after parturition. I find it recorded by Mr. Havers in the *Medical Times and Gazette* for February

14, 1852:—A delicate lady, aged 34, was delivered of her second child after a natural and easy labour. The removal of the afterbirth was attended with some little difficulty, and was followed by a gush of blood so sudden and violent as to place her life in imminent danger. This took place on the 18th of August, and she progressed favourably till the morning of the 23rd, when her attendant "found her restless, her countenance sallow, her eye unusually bright and wandering, and her manner catching and irritable. She said she had passed a bad night, which she referred to the fullness of her breasts, producing a feeling of palpitation and distress at the pit of the stomach. Her tongue was slightly coated, and her pulse as usual quick and weak." These symptoms subsided under an alterative dose, followed by aperients, and matters went on well till the morning of the 30th. "She had been on the sofa and easy chair each day, was in good spirits, and apparently in good health. On that day she was better than usual; she made her lunch at an early hour, and told her nurse she was so well she would dress herself without assistance; while in the act of dressing she fell on the bed; the nurse observed some frothing of the mouth and slight convulsion of the face. She spoke feebly once, then laid herself back and died, the whole circumstances occupying but a few seconds." Mr. Paget assisted at the post-mortem examination, which took place forty-four hours after death. "With the exception of the cicatrix of an old abscess in the apex of the right lung, and the heart to be just referred to, the organs were generally healthy. The muscular structure of the heart was pale and thin, especially that of the right ventricle, which contained some dark blood. Each of the pulmonary arteries contained a clot of blood, nearly filling the calibre of the vessels. The chief clots were about an inch and a quarter in length, mottled and firm, and in some instances slightly adherent to the sides of the vessel. In tracing the divisions of the artery numerous other clots were found of the same character as the larger ones, and extended even into the smaller ramifications of the arteries." Mr. Paget seemed to think these clots had been two days in existence previously to the death of the patient. I cannot hazard any comments upon this case. It is the first recorded example of death in the puerperal state from the cause assigned: if, however, Mr. Paget's theory as to the etiology of obstruction of the pulmonary arteries be sound, it would lead us to infer that this lesion may have a larger share in the production of the sudden deaths of childbed than is at present at all suspected.

Mr. Paget, as we have seen, has expressed the opinion, that some alteration in the constitution of the blood—such, for instance, as is engendered by Bright's disease—predisposes to the arrest and coagulation of the circulating fluid in the pulmonary arteries. Now, it is well known that in most cases of phlebitis, contamination of the blood is a marked pathological feature; and the highest authorities agree in referring phlegmasia dolens to a phlebotic origin. This may in some measure help to throw light upon the cause of sudden death in this disease—an accident which has been noticed by many authors as one to be apprehended from any undue exertion on the part of the patient before convalescence is thoroughly established. An instance of sudden death under these circumstances occurred in this city some years ago. The patient had had a severe attack of phlegmasia dolens, but the acute symptoms having been subdued by appropriate treatment, she was progressing favourably towards recovery. There was some diarrhoea present, however, and one day, in the absence of her nurse, she very imprudently got up to the night-chair, whereupon she immediately fell forwards on the floor, and before medical assistance could be obtained life was extinct. These facts I had from an accoucheur of eminence who had seen this patient occasionally during her illness. Connected with this subject there is a practical observation of some importance which it is well to mention, and it is this: patients who have suffered from uterine or crural phlebitis should be strictly enjoined not to make any considerable bodily exertion, or assume the erect posture, except in a

very gradual manner, and after convalescence is established. Disregard of this may, as we have seen, be attended with fatal consequences, and has often been known to induce syncopal attacks of a very alarming nature.

It is generally considered that where there exists organic disease of the heart or great vessels adjacent, the worst consequences are to be apprehended from the effects of parturition. That this should be the case cannot be matter of surprise to any reflecting mind. The simple act of delivery, as every one here knows, necessarily entails great alteration in the distribution of the blood, inasmuch as the vast demand of the uterus suddenly ceasing, the supply which it hitherto received is thrown upon the system at large. This surplus quantity of blood is in a considerable measure accommodated by the greater distensibility of the vessels of all the other abdominal and pelvic organs, owing to the immense reduction of the volume of the uterus, and the consequent diminution of pressure on these viscera. This is probably the arrangement by which any inordinate or injurious afflux of blood to the cardiac chambers is guarded against. The opposite condition, or a failure in the quantity of blood reaching the heart, is of considerably more danger, and one which must occur if, as often happens, the discharge of blood after delivery be at all copious, or even a little beyond what is natural. In some structural diseases of the heart, the simple act of normal uncomplicated parturition is sufficient to produce fatal effects. In the impaired state of its functions, the suffering organ is unable to accommodate itself to the least fluctuation in the quantity of blood reaching the auricles. Such, I think, was the following case, which was communicated by Dr. McCowan to the Edinburgh Obstetric Society. On the June 16, 1845, he was requested to visit Anne Barker, *ætat.* 21, stated to be in labour of her first child. He found her labouring under spurious pains, which subsided under the usual treatment. On the 19th she had symptoms of pleuro-pneumonia of left side, for which she was bled to ten ounces and cupped to four ounces with immediate relief. About three o'clock of the morning of the 20th, labour commenced and proceeded naturally and speedily till nine a.m., when she was delivered of a still-born male child, and instantly expired. *Post-mortem.*—"The body presented a generally oedematous appearance. On opening the thorax, the pericardium was found distended with a dark fluid. The heart was much enlarged, extending about two inches to the right of the sternum. The right ventricle very thin and dilated. The aortic opening could with difficulty admit the point of the little finger; the valves were hard and cartilaginous. The whole heart was filled with coagulated blood. The surface of the pleuræ were strongly adherent; the greater part of the left lung was hepatized. The uterus and other organs seemed healthy." At the same meeting, Dr. Simpson related a case closely resembling this, the patient suddenly expiring immediately after the expulsion of the child. The existence of cardiac disease had long been suspected. Cases of this kind are not very rare, so that I need not multiply examples.

But it is not only at the moment of delivery that danger is to be dreaded where there exists serious cardiac disease. Experience shows us that for some days subsequent to this event the injurious effects of parturition may be felt by the diseased organ. To illustrate this, I shall relate two or three cases. The following was obligingly communicated to me by Dr. Fitzpatrick. I relate it here, partly because the distressing symptom of orthopnea was unquestionably produced by the disease of the heart; but chiefly on account of its general interest. It may fairly, however, be disputed whether, or how far, her subsequent death is to be ascribed to the organic affection under which she laboured: "Mrs. E., aged about 35, had been the subject of cardiac disease for some months. Being in the fifth month of pregnancy, she was attacked, in April, 1850, with palpitations and occasional dyspnoea; general oedema also existed. Medical treatment considerably relieved these symptoms, but the organic disease was so confirmed that I

prepared her family for a fatal result. On the 28th of August, after a favourable labour of three and a half hours' duration, she was delivered of a son. The placenta came away naturally, but immediately after its expulsion she was seized with sudden dyspnoea, which obliged her to start up from the recumbent posture. This movement brought on uterine hæmorrhage, and for two hours I had the most anxious and distressing attendance I ever experienced in practice. The difficulties of the case may be appreciated when it is recollected that the means for arresting the hæmorrhage aggravated the dyspnoea. However, I ultimately succeeded in allaying the asthmatic paroxysm so far, that the patient was able to lie down, and appropriate treatment then arrested the hæmorrhage. She had no return of the dyspnoea, passed a good night, and expressed herself as feeling better than she had done for some time. On the third day after delivery, the breasts being full and tense, I directed a purgative which acted well, and relieved her. She continued to progress favourably on the fourth day. On the following day I found the patient in a very altered condition. She was sitting up in bed, complaining of orthopnoea and of wind in her stomach; the face was pale and waxy; countenance anxious; pulse weak and rapid; the abdomen was enormously distended with flatus, but free from pain. I learned that she had imprudently dined on chicken, and took some wine the day before; and the symptoms I have detailed commenced early in the morning, after a restless night. The usual treatment for tympanitis failed in giving the slightest relief. The tension of the abdomen increased to the utmost possible extent, and the patient died at four o'clock p.m. The immediate cause of death seemed to be the arrest of respiration from the great distension of the abdominal cavity. I am not prepared to say what influence the disease of the heart may have had in causing death, as there was no post-mortem examination." Though the latter part of this history does not directly bear upon the subject now under examination, still I am sure I shall be excused for introducing it. The extraordinary gaseous distension of the abdomen—so great indeed as to be the presumptive cause of death—is a very remarkable feature in the case. Connected with the pathology of meteorismus, and its mode of production, there is much yet to be learned. My friend Dr. H. Kennedy, the cause of whose absence from amongst us this evening we all must lament, had, I know, drawn up a memoir on this subject, which he intended reading at the Obstetric Society, had not his unexpected illness prevented him. In the *Lancet* for March 20th, Mr. McNicholl of Birkenhead, details a case, of which the following is an outline:—A lady, aged 40, was delivered naturally on the 19th of January. Convalescence was completed in twelve days. Two days after this, when in the act of getting out of bed, she suddenly exclaimed that something had given way internally, and expired in twenty minutes. On examination of the body, the cause of death was found to be rupture—of the right ventricle. Some degree of fatty degeneration of the heart existed.

On two occasions in my own experience I have seen a patient almost die under my hands immediately after delivery, from no other discoverable cause but this complication of diseased heart. One of these cases was seen by the late Dr. Labatt, who entirely concurred in the view I had taken of it. A few years ago a very sudden death occurred apparently from this same cause, which created much sensation, as the lady was highly connected. On the tenth or twelfth day, after a most favourable accouchement, she suddenly, when up, complained of being unwell. The nurse assisted her into bed, and in the space of three or four minutes she ceased to live. This lady was known to labour under organic disease of the heart.

I have now, sir, finished, though by no means completed, the task I proposed to myself. Let it not be said in disparagement of my endeavours that nothing has been brought forward which was new or unknown. If nothing were omitted of what is already known, I should have much cause to be satisfied, as next to calling the earnest atten-

tion of practitioners to this subject, my object has been to give a brief *resumé* of the different circumstances under which the life of a patient in childbed may be abruptly terminated, and to develop some of the hidden sources of danger which beset the puerperal state. To recapitulate, then, the probable causes which may operate in effecting this result are—1, Idiopathic asphyxia; 2, the shock of parturition; 3, syncope; 4, mental impression; 5, air in the veins and heart (?); 6, the formation of a coagulum in the heart; 7, clots in the pulmonary artery; 8, phlegmasia dolens; and 9, morbis cordis. From the observations which have been made under each of these heads, it is needless to reiterate here the absolute importance of careful and minute examination of the body in every case, if we would know with anything like certainty the cause of death. I rejoice to see that this subject is beginning to attract in other quarters the attention it so well merits. At a recent meeting of the Surgical Society of Paris it formed the basis of a paper by M. Robert, who narrated three examples which had occurred in his own practice of sudden death on the ninth and sixteenth days after delivery without any discoverable cause. In the discussion which ensued, MM. Dubois, Moreau, and Baudelocque, stated that they had each met with similar instances. Recorded examples of this accident are more frequently met with of late, because practitioners are beginning to get the better of that "*mauvaise honte*" (I can call it by no other name) which kept them from publishing these unfortunate cases, and this increase of facts will, we may hope, lead to clearer and more satisfactory views as to the causes of sudden death in the puerperal state.

#### CORK MEDICAL SOCIETY.

THIS Society held its usual meeting at the Royal Cork Institution, on Wednesday, the 21st ult. In the absence of the President,

Dr. HAINES took the chair.

Dr. COTTER read an interesting paper on diseased testicle, and exhibited a testis which had been removed in consequence of a fungous growth which Dr. Cotter seemed to consider of a benign character, although the patient had for a long time suffered from the disease, and at the time of its removal was greatly prostrated. The patient recovered. The testis and morbid growth, immediately after removal, weighed over two pounds. The paper led to an interesting discussion, and Dr. Cotter promised at some future time to follow up the subject.

Dr. TANNER exhibited an ingenious forceps for the removal of polypus in the nares.

Dr. HEWITT presented to the Society a boy, aged 15, who, some months ago, was kicked on the nose and temple by a cow. At the time no inconvenience, beyond some hæmorrhage from the nares, occurred, and for three or four days the boy went about his usual avocations. On the fourth or fifth day he complained of giddiness, and lost the power of speech. Living some miles from medical assistance, he was taken in a car to the next dispensary, when his head was shaved and blistered, some medicine given him, and subsequently tartar emetic ointment was rubbed over the scalp. However, up to the present, although the boy (who looks to be strumous, and is rather attenuated) is in possession of his hearing, and has perfect use of the tongue, and seems intelligent, has never been able to articulate. Some of the members tried to make him pronounce the letters of the alphabet, but he could not effect it. His father, who accompanied the lad, stated that on one occasion his mother heard him speak in his sleep! The case is worthy of further investigation.

The members separated at ten o'clock.

**TOOTHACHE.**—M. Desterne says that the most intense toothache, connected with decayed teeth, is relieved in a moment by the magic touch of the membrana tympani with a blunt probe. Neuralgia of the face is relieved in the same way. These effects are supposed to be obtained by the influence of the chorda tympani nerve.

## DISTRIBUTION OF THE MOTOR NERVES, AND MOVEMENTS OF THE EYEBALLS.

By J. STRUTHERS, F.R.C.S., Lecturer on Anatomy, Edin.

THAT there is a meaning in the peculiar distribution of these nerves among the muscles of the orbit, cannot be doubted. It is singular and constant, and is found to be the same in all vertebrate animals. This is stated by writers on comparative anatomy, and I have always found it so. The fourth nerve is never distributed to any muscle but the superior oblique, and to this muscle it always goes, although the muscle has a very different position in the three lower classes of vertebrate animals. But the sixth nerve in most mammals, and in birds, supplies additional muscles; in the latter, the muscles which move the third eyelid, and in the former, the retractor or suspensory muscle of the eye. When this muscle is single, a single division of the sixth nerve enters it; when it consists of four separate slips, intermediate to the recti, two or three delicate filaments leave the sixth to supply them. It is worthy of remark, that the part of the nerve which goes to the retractor muscle is less than a third of the whole trunk, whilst the bulk of the muscle is usually much greater than that of the external rectus.

In inquiring into the function of these nerves in connexion with the motions of the eyeballs, it is necessary in the first place that we determine upon the action of the muscles which they supply.

About the actions of the recti muscles there can be no doubt or obscurity, providing it be granted, first, that each turns the eye in its own direction; and secondly, what is equally evident, that two neighbouring recti turn the eye diagonally between them; and that thus all the diagonal as well as the direct movements are performed; a view which would never have been doubted but for the apparent necessity of discovering some use for the oblique muscles. And as to the oblique muscles, I think, from what is stated in my paper on this subject, it is impossible to avoid the conclusion,—in accordance with a view which is older even than the time of John Hunter, who specially supported it, notwithstanding which it had again fallen into disrepute,—that the use of these two muscles is to perform *lateral rotation*,—i.e., to roll the eye on its antero-posterior axis. This becomes still more evident when we descend below the mammalia, when the superior oblique is seen to be no longer reflected over a pulley, but lies at the forepart of the orbit, simply as the counterpart of the inferior; and it is at once evident, not only that these two transverse muscles pull the eye round about on its axis, but also that they cannot act so as to change the direction of the axis, so as to assist or partly supplant the recti in the manner in which they are commonly supposed to do so in man. It is likewise, I think, made evident that such a motion of the eye, as Hunter supposed, is necessary, during the side inclination of the head, to prevent the impression of the object changing its place *circularly* on the retina. It is possible that, from the slight variations they present, in their point of attachment and in their direction to the axis of the eye, in different animals, they may associate their rotatory movement with a slight change in the direction of the axis. As to this I cannot speak positively, but I hold that, whatever minor actions they may or may not have, the action of these muscles is to rotate the eye on its axis; that, in short, this is the purpose for which they were provided. I arrived at this conclusion chiefly from the consideration of their comparative anatomy, and since then, I find additional evidence of the correctness of this view from the writings of Jacob and Longet, without reference to comparative anatomy, which are deserving of notice here also from their bearing on the subject of paralysis of the motor nerves of the eye. Dr. Jacob, in a very instructive paper on the muscles and nerves of the eye,\* observes:

“The two oblique muscles, not running from the inside of the orbit directly outward, but inclining backward, until they become attached to the posterior part of the eye, not only cause the sphere to revolve on its longitudinal axis, but probably change the direction of that axis; the inferior directing the cornea perhaps a little upward and inward, and the superior a little downward and outward. I have, however, great doubts as to the actual production of this effect. That the inferior oblique causes the eyeball to revolve round its longitudinal axis, may fairly be inferred from its attachments, but that it alters the direction of that axis in any considerable degree, cannot be so easily admitted. We cannot observe the action of this muscle distinct from that of the others, but we can that of the superior oblique. In cases of paralysis of the three straight muscles, the inferior oblique, and the elevator of the upper lid, from disease affecting the third pair of nerves, the action of the abductor supplied by the sixth nerve, and of the superior oblique supplied by the fourth, remains unimpaired. The patient unable to raise, depress, or turn in the eye, or elevate the upper lid, turns it out as effectually as ever, when directed to do so; and when directed to look downward, the action of the superior oblique is clearly distinguished. It is a delicate rotatory motion, with perhaps a very slight inclination downward and outward. Of this I have now no doubt, having repeatedly within the last two years observed it, and pointed it out to the students.” And, again, in connexion with a case of complete paralysis of the muscles supplied by the third nerve, he observes—“On directing her to look down, the eye is distinctly twisted from the nose toward the temple without any visible direction of the pupil downwards. It is a mere rotatory motion.” Longet refers to several writers as having held this view regarding the action of the oblique muscles:—MM. J. Guerin, 1840; Huech, 1841; Helie, 1841; and more especially to M. Szokalski, who has written a memoir on the subject. The nature of the motion seems to be very clearly apprehended by them, and they appear to see the necessity for this motion when the head is inclined from one shoulder to the other, the eyes being kept fixed on some object. Longet also refers to M. Berard's view that, in this case the superior oblique of one side will act at the same time as the inferior of the other side; and adds that “it does not seem to me to be possible to perform voluntarily the rotatory motion of the eye, of which we spoke above, when the head is fixed.”

In connexion with the point now under consideration, I shall next refer to the subject of *paralysis of the fourth nerve*, or superior oblique muscle. For doing so here I need offer no apology, as the subject is one regarding which very little is known. Those who look for the symptoms of paralysis of this nerve to accord with Sir C. Bell's now abandoned theory that the muscle is concerned in an involuntary upward motion of the eye, must necessarily be mistaken; but more generally paralysis of the fourth nerve is passed over as a subject of which nothing is known, whilst the symptoms of paralysis of the third and sixth nerves are simple and well understood. The only writings bearing directly on the subject of paralysis of the fourth nerve, with which I have met, are those of Dr. Jacob and M. Szokalski as quoted in Longet's work. Dr. Jacob's remarks scarcely admit of condensation. He observes:—“Paralysis of the superior oblique muscle has not been noticed, because it is not easily detected. I have already said that I believe the action of this muscle to be very delicate, and confined to communicating a slight rotatory motion to the eye. The grounds upon which I have arrived at this conclusion are, repeated observations of cases of paralysis of the other muscles, from diseases of the third. It must, I think, be admitted that when the levator, depressor, adductor, and inferior oblique muscles are paralysed, the eye must remain fixed, unless moved by the abductor, or superior oblique. That this is the case, an attentive examination of an eye affected with what is commonly called *ptosis* proves. The eye is turned out by the action of the abductor, supplied by the sixth nerve, as

\* On Paralytic, Neuralgic, and other Nervous Diseases of the Eye. By Arthur Jacob, M.D. From the DUBLIN MEDICAL PRESS of January 6, 1841.

perfectly as ever, and when the patient is directed to look downward, or toward his shoulder, the cornea is seen distinctly to revolve, with little if any depression of the pupil. In other words, the eyeball is turned round its antero-posterior, or longitudinal axis. In this I think I cannot be mistaken, as I have repeatedly called those about me to observe the fact, in order to bear testimony to it. I have alluded above to a case in the City of Dublin Hospital, in which the four straight muscles of the eye, with the elevator of the upper lid, and probably the inferior oblique, were paralysed from disease of the third and sixth nerves within the skull, and in which this delicate rotatory motion was obvious. If the action of the superior oblique be to turn the eye downward and outward in a considerable degree, there could be no difficulty in demonstrating that action, in the case of the other muscles to which I allude; yet this cannot be done, but on the contrary the delicate rotatory action to which I allude is the result of the effort. The next question, however, is, whether paralysis, either sudden or slow, of the superior oblique, takes place or not; and this question is not, I admit, so easily resolved by demonstration. One thing must, however, be admitted, and that is, that it is most improbable that this superior oblique muscle, and the fourth nerve which supplies it, should be exempted from disease or its consequences, while the other nerves and muscles so frequently suffer. On the contrary, looking at the remote origin of the nerve, the length of its course, and its small dimensions, we should rather expect to find it more frequently engaged than any of the rest. If the action of the muscle be what I say it is, it is no wonder that paralysis of it should be difficult of detection, while all the other muscles are in a state of activity. Its loss is not perceived in the multiplicity of other motions. There is, however, I think, good grounds for supposing that the consequences of such paralysees are occasionally evident. There are certain cases of anomalous and unintelligible defects of vision, which can scarcely be accounted for in any other way than by attributing them to this cause. I allude particularly to double vision with great confusion of sight, and with little or no squint."

Dr. Jacob then refers to several such cases. One patient had double vision. When he looked downwards, he lost sight of objects, while he saw well enough on looking upwards. He saw quite well with either eye singly. In three cases the patients saw near objects correctly, but those at some distance appeared double. Another where vision was good with one eye closed, but imperfect when both were open; and it is not stated that there was any squint. Dr. Jacob farther states that he has met with many similar cases; but not taking this view of them at the time, did not pay that attention to them he now would. Although I have thought it right to quote the points of interest in these cases, which the author merely suggests might possibly have been of this nature, yet they do not strike me as exactly the symptoms which we would expect to arise from want of action of the superior oblique muscle.

According to M. Szokalski, paralysis of the fourth nerve is rare as a separate condition; but he has seen it several times along with paralysis either of the third or sixth pair. He relates two interesting cases, which I shall translate entire:—

"Case 1.—The eyes of the patient have no trace of lesion, their mobility is in no way constrained, and they can be directed easily to all sides, which proves that there is no anomaly in the straight muscles of the two eyes. The two pupils are of equal size, and equally dilatable. Nevertheless, the centre of the *left* cornea manifests a tendency to be placed a little lower down than the right; there is double vision, and constantly *one image of the object is placed above the other*. If the right eye is shut, the upper image disappears; if the left eye, the lower image ceases to be visible. The two images resemble each other always so exactly, that the patient learns only by judgment and habit, that the inferior is false. When the head is inclined to the left, the images separate more and more; but if it is inclined to the right only one image is seen. Since

I have pointed this out to him, adds M. Szokalski, he goes with the head inclined to the right; formerly he managed by keeping one eye shut.

Case 2.—An attentive examination showed to M. Sichel and myself, that the two eyes are perfectly moveable in every sense. The patient states that every object seems double to him, in such a manner that he perceives two images, *the one above the other*; these two images separate in proportion as he retires from the object; the lower image appears less distinct. Some vessels were found injected in the external corner of each eye; we looked carefully whilst we moved the patient's head alternately to the left and to the right, holding it by the temples, and we remarked then that *the left eye remained attached to the wall of the orbit, which followed the movements of the head*, whilst the right eye underwent a rotatory movement in the orbit. The patient was astonished to see single when he inclined the head to the right."

"It appears impossible," says M. Szokalski, "to explain these phenomena otherwise than by paralysis of the left superior oblique muscle." And M. Longet concludes—"According to these observations of M. Szokalski, the symptoms of paralysis of the fourth nerve are the following:—1. The impossibility of the rotation of the eye in the orbit. We recognize that impossibility when the patient is directed to bend his head alternately from side to side, while he keeps his eyes fixed on some object; we see then that the affected eye remains fixed, and that it does not follow the rotations of its fellow. 2. There is constantly double vision, and the two images are placed *one above the other*; the affected eye furnishes the lower image. 3. The double vision disappears when the head is inclined to the side away from the affected eye."

Now, if the report of these cases is faithful, and they seem very circumstantially related, they form a very interesting contribution to the subject of paralysis of the fourth nerve. Since my attention was drawn to this subject, I have not had an opportunity of verifying or testing these observations; but looking theoretically to the matter, I should think that the passive state of the eye, whilst the head was being bent to the side, would require to be carefully looked for, to be noticed. According to our view of the action of the oblique muscles, when the head is bent over to the right, the right superior oblique and the left inferior are in action, so that the upper part of the right eye is turned round towards the inner canthus, and the upper part of the left is turned round towards the outer canthus, so as to counteract the chiefly circular displacement which the picture would otherwise undergo on the retina. Now, were the movement a purely rotatory one, without the least depression or elevation of the axis, we should expect to find, not double vision with one object above the other, but confused vision, one image of the object being across the other; that, for instance, a pencil, held up, should appear more or less like a cross. But as a purely rotatory motion, without any change in the direction of the axis, would be required only if the head was being bent round on an axis exactly corresponding to the axis of the eye, which can never be exactly the case, at least with both eyes at the same time, we can readily understand why the oblique muscles, whilst they roll the eye round, may be employed also slightly to alter the direction of its axis, and why therefore paralysis of one of these muscles should cause double vision with separated images, unless when its antagonist on the same side is in action; that is, for instance, why paralysis of the right superior oblique should cause a second image to appear, belonging to the right eye, when the head was bent over to the same side, or unless when it was turned to the opposite side. Just in the same way as, in paralysis of the right sixth nerve, the patient has double vision when he looks to the right, but sees single when he looks to the left side. I cannot, however, see, still merely reasoning on the matter, why in paralysis of the superior oblique, the false image should necessarily be situated *below* the other, because, if the superior oblique has any little power in changing

slightly the direction of the axis whilst it is rolling the upper part of the eye round towards the inner canthus, it will certainly be downward; and when the muscle is paralysed, there would be a want of this slight downward motion, and the false image should therefore be, if not above, at least not below, the other. This I infer from the experiment of causing double vision by pressing one eye in different directions. If the right eye be pressed inwards with the finger, the false image moves to the left. If the eye be pushed up, by pressing, for instance with the end of a small key, deeply between the lower lid and the orbit, the false image moves up. And if, in a similar way, by pressing in deeply between the orbit and the upper lid, the axis be depressed, the false image will move down, and appear below the one from the untouched eye, somewhat as in M. Szokalski's cases of presumed paralysis of the fourth nerve.

My object in presenting these theoretical considerations, however, is not to endeavour to prove the superior oblique not to have been affected in these cases, but to show on the one hand that this relative position of the two images, in diplopia, is not to be regarded as essential to establish the case as one of paralysis of the superior oblique, a condition which might give rise to various positions of the false image; and on the other hand, that such a relative position of two images does not necessarily, of itself at least, point to the superior oblique as the muscle affected, but might be due to a slight inequality in the action of the upper or lower recti muscles.

Before leaving the subject of our view of the action of the oblique muscles, I may illustrate it by one other reference to a diseased condition, as described by Dr. Mackenzie of Glasgow, under the title of "Oscillation of the Eyeball." This oscillatory movement is rotatory round the antero-posterior axis, and is not to be confused with the oscillatory movement from side to side by the lateral recti, which is not uncommon, and has received a different name. He observes, "in oscillation the eyeball is affected with an almost perpetual rotatory motion round its antero-posterior axis. The patient is not conscious of this motion, from any particular feeling he has in the eyes, nor can he restrain it. It goes on even when the lids are closed, but it ceases during sleep. The motion varies in extent, from a scarcely perceptible degree, to perhaps nearly a quadrant. In some cases the motion seems to be rather from side to side, but often so small in degree and so rapid, that it is difficult to say what is exactly its direction. In general, it is pretty distinctly rotatory, and seems to be produced by the antagonising action of the obliqui, the recti having lost, in a great measure, their control over the eye."—*Edin. Monthly Jour.*

## ON REINSCH'S PROCESS FOR THE DETECTION OF ARSENIC.

By Professor RAINY of Glasgow.

THIS process consists in boiling the suspected fluid with about one-tenth of its bulk of muriatic acid, along with copper. The arsenic is deposited on the copper in the form of a steel-gray film.

It is generally supposed that this process is equally applicable to all the compounds of arsenic soluble in dilute muriatic acid; and that, in all circumstances, it detects the presence of the metal with a delicacy more than sufficient for every practical purpose.

Soon after the publication of Reinsch's method I made various experiments, with the view of determining the limits within which its indications might be relied on. The result was unsatisfactory, for while in some cases it seemed to be fully as delicate as the method of Marsh, in other cases I failed to obtain the metallic deposit where the arsenic was present in a much higher proportion. Similar observations have been made by others, for it is stated by Fresenius and Van Babo, that "the presence of nitrates and various salts of mercury and other metals renders the separation of arsenic by copper difficult or even impossible." It seems also to be a general opinion, that when the proportion of arsenic is extremely minute the process of Marsh is decidedly preferable.

It is obviously important that the cause of such discrepancies should be investigated, as the great rapidity and simplicity of Reinsch's process render it peculiarly suitable for medico-legal investigations, and give it a decided superiority over every other, if it can be conducted in a manner that will ensure equal delicacy.

The following experiments were made with the view of ascertaining the cause of these discrepancies, and if possible, the means of preventing them. The copper was used in the form of very thin foil, which was easily cleaned and polished, so as readily to show any change of colour; the fluid usually contained *one tenth* part by measure of muriatic acid of the ordinary strength, except when the object was to ascertain the effect of varying this proportion; and in order to prevent any diminution of the fluid, or any change in its strength during the boiling, a condenser containing cold water was placed closely over the mouth of the vessel in which the process was carried on.

1. My first object was, to ascertain the *extent of copper surface* that can in the most favourable circumstances be distinctly coated with a given quantity of arsenic. The results were very uniform. *One thousandth of a grain* of arsenious acid gave a full steel colour to *one square inch* of copper surface. When *two square inches* of copper surface are used with the same quantity of arsenious acid, the effect is still distinct; but the deposit is in these circumstances so thin that there is a tinge of yellow, apparently from the copper shining through or not being uniformly coated. *Two square inches* of copper surface, then, is the utmost extent of copper surface that can be distinctly coated by *one-thousandth of a grain* of arsenious acid; and it can be proved that the thickness of the film of deposited metal, if consisting merely of arsenic, does not exceed  $1-4000000$ th of an inch.\*

It follows from this result, that if the extent of copper surface be too great relatively to the arsenic present, no distinct deposit will be obtained; thus a fluid containing one-thousandth of a grain of arsenic, with *three square inches* of copper surface, might give a tarnish, but no distinct coating.

2. The effect of *dilution* was next examined. When the fluid was to the arsenic as *one million* to one, the deposit was distinctly formed in fifteen to twenty minutes. Thus, one-thousandth of a grain of arsenious acid in one thousand grains of fluid, and consequently constituting one-millionth part, gave a distinct coating to one square inch of copper surface in twenty minutes. The same quantity of arsenious acid, in two thousand grains of fluid, also gave a deposit on the copper; but it was less distinct, and required a longer time. It appears, then, that with a dilution of one million times, the effect is distinct and prompt, and when the dilution is carried to two million times it is indistinct and tedious. A dilution of two million times appears to constitute the practical limit in Reinsch's process. By continued boiling it is easy, of course, to concentrate the fluid, so as to bring the dilution within these limits, if arsenic be present in any proportion, however small; for there appears to be no loss of arsenic by evaporation, during the boiling.

3. The *proportion of muriatic acid* in the solution has a considerable influence on the *rapidity* of the deposition, and even on its *production*, when the arsenic is in very minute quantity. Thus if the arsenic is less than one-millionth, the process is very slow in a fluid containing one-tenth muriatic acid of the ordinary strength; but when it amounts to one-seventh or one-sixth, the deposition is much accelerated. And in solutions in which the quantity of arsenic is so small that with the ordinary proportion of acid no deposit is obtained, the copper becomes distinctly coated if the proportion of muriatic acid is doubled.

4. From these observations it would follow that the rapidity with which copper acquires a distinct arsenical

\* I afterwards found that the film contains a large proportion of copper, and consequently the thickness will be greater than is stated above.

coating is directly as the proportion of arsenious acid and also of muriatic acid in the solution, and inversely as the extent of the copper surface.

5. As copper receives a coating of a similar colour from other metals, from sulphur and sulphuretted compounds, the mere formation of such a deposit cannot be considered a conclusive proof of the presence of arsenic. It is merely a convenient method of *separating* the suspected substance, in order that it may be subjected to the appropriate tests. The most satisfactory of these tests are, the formation of a white crystalline sublimate by heating the coated copper; the solution of this sublimate in water; and its conversion, by the appropriate reagents, into arsenite of silver, orpiment, and arseniate of silver, all of which are very easily recognized by the peculiarities of their colour and other properties. In estimating the value of Reinsch's process, it is therefore necessary to ascertain, not only the smallest quantity and the utmost dilution under which it can be separated and distinctly exhibited on copper, but also the smallest quantity which, when so separated, can be satisfactorily subjected to the conclusive tests.

In repeated experiments I found that one-thousandth of a grain of arsenious acid in one million times its weight of fluid could be separated as a distinct deposit on copper. The copper thus coated, when heated gently in a small tube, yielded a slight but distinct sublimate, most obvious on a black ground, and which, with a magnifying power of ten to twenty diameters, was found to consist of crystals with triangular facettes, and which, when dissolved in water, yielded orpiment and the red arseniate of silver, when treated with the appropriate reagents.

This I believe to be as great a degree of delicacy as has actually been obtained by the more tedious and troublesome process of Marsh, and is more than sufficient for every practical purpose.

6. When investigating the delicacy of Reinsch's process, I prepared quantities of very dilute solutions of arsenious acid, varying in strength from 1-10000th to 1-100000th, and kept these solutions in readiness for the experiments which I had planned. When first tried with copper and muriatic acid, they gave results entirely conformable to those already stated. A portion of any of these solutions, containing one-thousandth of a grain of arsenious acid, when diluted so that the fluid amounted to a million times the weight of the arsenic, gave a distinct and rapid deposit on the copper; but afterwards I could obtain no deposit from larger quantities of arsenious acid, though in a more concentrated state. As an example, a portion of solution containing 1-200th of a grain of arsenious acid in 200 grains of water, and consequently with a dilution of one in forty thousand, gave *no deposit whatever* when boiled in the ordinary way with copper and muriatic acid for upwards of fifteen minutes. In this case, the surface of the copper was only one-eighth of a square inch, and therefore could not interfere with the result by its too great extent.

I was perplexed with the apparent inconsistency of these results with those previously detailed, and began to suspect that I had been misled in my first estimate of the extreme delicacy of Reinsch's process. But after repeated trials, I found the difference to depend on the *length of time that the solution is kept*. *Very dilute solutions of arsenious acid become gradually less and less sensitive to Reinsch's process*, so that after several weeks no deposit can be obtained on copper from solutions containing arsenic in the proportion of one in *fifty thousand*, or even one in twenty thousand.

7. I was thus led to examine whether these dilute solutions underwent any appreciable change in their chemical properties, and found that with nitrate of silver they gave a grayish cloud; when concentrated by evaporation to a small bulk, the residual fluid *strongly reddened litmus*, and when evaporated to dryness, left a white stain, which did not sublime at a low red heat. This stain re-dissolved in a few drops of water, formed a solution which *still strongly reddened litmus*, and which, on the addition of a strong solution of nitrate of silver, gave a *brick-red precipitate*.

These experiments clearly indicate the conversion of *arsenious acid into arsenic acid*.—*Trans.*

## EXTRACTS FROM A PAPER ON DEATH FROM CHLOROFORM.

By JOHN SNOW, M.D.

THERE is no reason to believe that any of the accidents from chloroform have arisen from the continued exhibition of the vapour well diluted with air. On the contrary, the sudden manner in which the alarming symptoms came on in every case, shows that they were produced by the respiration of air containing not less than eight or ten per cent. of the vapour; and from the history of the cases, it is most probable that the heart was disabled, in most instances, by the direct action of the chloroform. No systematic means were taken for properly diluting the vapour with air, in any case in which death has happened. The chloroform was exhibited on a handkerchief, or towel, or piece of lint, in all the cases but three; and, in two of these, it was not applied by a medical man. In order to show how easily accidents may happen with chloroform, I must beg attention to a few circumstances connected with its physical as well as physiological properties. On a former occasion, I showed, both from experiments on animals, and the amount of chloroform consumed in inhalation, that the average quantity of it in the blood of an adult patient, when insensible to the surgeon's knife, is about eighteen minims, and that, if twice that amount were present in the blood, it would suffice to cause death, even if it were uniformly distributed. Now thirty-six minims of chloroform, when in the form of vapour, only occupy thirty-seven and a half cubic inches, or very little more than a pint. It is true that the vapour of chloroform does not exist in a separate state at the ordinary temperature and pressure of the atmosphere; but air, when saturated at 60 degrees, contains rather more than twelve per cent. of the vapour; and supposing the air to contain ten per cent., which it does when the chloroform dew point is at 55 degrees, the thirty-six minims would be contained in 375 cubic inches of air, more than half of which might possibly be in the lungs at one time.

The quantity of blood contained in the adult human being has been estimated by M. Valentin to average thirty pounds; and the thirty-six minims of chloroform, mentioned above, is only one minim and one-fifth, or one cubic inch and a quarter of vapour, for each pound of blood measuring about twenty-seven cubic inches. Consequently, if a pound or two of blood should be impregnated to this extent with chloroform, and sent to circulate in the nervous centres, the respiration might cease before the remainder of the blood should be equally charged with vapour. Moreover, I ascertained that a little more chloroform than this—viz., one-eighteenth part, as much as the blood will dissolve, or about a cubic inch and a half of vapour to each pound of blood—has the effect of stopping the contraction of the heart by its own influence. Now, 100 cubic inches of air, containing ten per cent. of vapour, if present in the air cells of the lungs, might yield this amount of chloroform to two or three pounds of blood, and still retain from five to seven per cent. It is easy to perceive, therefore, that death might be caused by a very small quantity of chloroform, if it were inhaled in a concentrated state; and, indeed, in the experiment No. 4, on the rabbit, related above, the action of the heart was arrested by three or four inflations of the lungs in so short a time that only a portion of the blood in the body could have become impregnated with the chloroform. The necessity of having the vapour sufficiently and systematically diluted with air, must therefore be evident. By such a plan, it is true, the patient cannot be made insensible in so short a time as was recommended by Dr. Simpson on the introduction of chloroform. Three or four minutes must be occupied in gradually and equally charging the blood with the requisite amount of vapour, but it is time well expended on the safety which it ensures.

The quantity of chloroform contained in the air the patient breathes during the use of the handkerchief, depends on the amount of surface wetted by the chloroform—on the proportion of air which comes in contact with the

wetted surface, or passes into the lungs without this contact—on the extent to which the handkerchief is now warmed by the breath, now cooled by the evaporation, and on the force with which the inspired air impinges on the surface of the handkerchief moistened with chloroform. It must be evident, therefore, that the amount of vapour contained in the air the patient breathes is very uncertain; and when it is stated that the agent has been administered in exactly the same manner in two cases in which the handkerchief has been employed, it would be more correct to say that it was exhibited in an equally uncertain way in each instance; and the difference in the result should be attributed rather to the want of uniformity in the method employed, than to a difference of susceptibility in the patients; for in administering chloroform by a uniform method, I find very little difference in the susceptibility of persons to its chief effects, whatever variety there may be in the symptoms they evince previous to becoming insensible.

There are two ways of effecting with certainty the sufficient dilution of the vapour with atmospheric air: the first and the best, is to employ a suitable inhaler; the second, is to dilute the chloroform with rectified spirit of wine before pouring it on a handkerchief or sponge. In the apparatus which I usually employ, the air which passes over the bibulous paper, when the patient breathes in the usual manner, takes up between five and six per cent. of the vapour of chloroform. I have ascertained this by weighing the inhaler before and after passing a measured quantity of air through it, in the way in which it passes in ordinary respiration, the loss of weight denoting the amount of chloroform which had evaporated. The apparatus is, besides, provided with valves, by means of which the air thus charged with chloroform can be still further diluted to any extent desired; and I always commence the inhalation with air containing very little chloroform, gradually increasing the quantity of vapour, and usually diminish it again as the insensibility attains the desired point, or at any time when the breathing is deeper and quicker than usual.

When chloroform thus diluted is first poured on a handkerchief, it is capable of yielding only a little more than half as much vapour to air which is brought in contact with it, as it yields in the undiluted state. As the process of inhalation continues, it yields less and less vapour, a weaker solution being left on the handkerchief. But by adding more of the mixture, the process goes on as at first. It is some little disadvantage that a combination of chloroform and spirit does not yield a uniform amount of vapour throughout the process of inhalation; but this is not of much consequence in using a handkerchief or sponge—the only method in which it is recommended—for this plan of administering chloroform does not admit of regularity or uniformity under any circumstances. During the removal of tumours of the maxillary bones and other operations on the face, in which I could not continue to employ the inhaler, I have been in the habit for the last three or four years of using chloroform diluted with an equal measure of spirit on a sponge, whenever I was aware beforehand of the nature of the case, and had time to be provided with it. At other times, I have poured only fifteen or twenty minims of chloroform on the sponge at once. The spirit is not at all irritating to the air passages, and its effects would not be injurious if it were inhaled in larger quantity; but owing to its small volatility as compared with chloroform, the patient does not inhale more than a few minims of it in the course of an operation, the greater part remaining behind on the handkerchief or sponge. I have often given chloroform thus diluted on a sponge or handkerchief to make animals insensible during physiological experiments, without ever meeting with the accidents which so frequently happen in giving undiluted chloroform to animals in the same manner.

The following list contains, I believe, all the cases on record in which death has been caused by the administration of chloroform. I have not included three or four

deaths which have happened to persons who have poured chloroform on a handkerchief and inhaled it when no one was present; for an accident is so natural a consequence of such a proceeding, that these cases do not come within the scope of this paper. The appearances met with after death in two of them will be noticed, however, further on:

Hannah Green, aged 15, near Newcastle, toe-nail operation; Mrs. Simmons, Cincinnati, U.S., extraction of teeth; Patrick Coyle, America, operation for fistula in ano; a young woman at Hyderabad, in Hindostan, amputation of the distal phalanx of a finger; Madlle. Stock, aged 30, Boulogne, opening an abscess; Charles Desnoyers, aged 22, Hôtel Dieu de Lyon, transcurent cauterization of diseased wrist; a young gentleman at Govan, near Glasgow, intended toe-nail operation; John Griffith, seaman, aged 31, New York Hospital, removal of hæmorrhoids; J. Verrier, aged 17, Lyons, intended amputation of finger; Samuel Bennett, labourer, Westminster, amputation of toe; Madame Labruné, Langres, France, intended extraction of tooth; John Shorter, aged 48, St. Thomas's Hospital, toe-nail operation; a girl named Jones, Shrewsbury, removal of eyeball; a young lady, Berlin, intended extraction of tooth; an artilleryman on board ship in the Mauritius, amputation of last phalanx of middle finger; Alexander Scott, aged 34, Guy's Hospital, removal of a portion of the hand; James Jones, aged 24, Cavan Infirmary, Ireland, intended amputation below the knee; John Holden, Stepney Workhouse, intended operation on penis; Madame Simon, aged 36, Strasbourg, extraction of teeth; Thomas Hutton, a mulatto, aged 45, Dreadnought Hospital Ship, extirpation of testis; Elizabeth Hollis, aged 37, Chipping Norton, Somerset, intended operation for cancer of os uteri. Total 21.

The above list contains two or three cases that have not appeared together in any previous table; whilst, on the other hand, I have excluded some deaths that have been attributed to chloroform, either because the fatal event was clearly due to something else, or because there are no means of deciding the point.

In a table given by Dr. Bouisson, the death of a child, aged 12 years, during amputation of the leg, at the hospital at Madrid, is given. But this is an operation which is sometimes preceded or accompanied by circumstances which may be fatal; and as the published particulars are not sufficient to enable me to decide, I have excluded it. Three of the insurgents who were wounded in Paris in June, 1848, died during operations in which chloroform was administered. Two of the operations were amputation at the hip-joint, and the third was amputation at the shoulder. As the operators do not attribute the deaths to chloroform, there is no reason why others should do so. The death of a patient of M. Roux has been attributed, not by that surgeon but by others, to chloroform, although it was quite certain that this was not the cause. A woman had a cancerous tumour of the breast removed under the influence of chloroform, and after she became conscious, M. Roux performed a protracted operation for the removal of some glands from the axilla, without the chloroform, and whilst the patient was sitting up to have a bandage applied, she fainted, and was dead. A death which occurred in the practice of Mr. Robinson, the dentist, I consider was not due to chloroform, because the patient showed none of the symptoms of its effects, and because the inhaler which was employed had not been approached nearer than an inch from the patient's face, whilst it might be held at that distance for a week without causing insensibility, much less death. On a former occasion I expressed an opinion that death was caused by syncope from mental emotion, occurring in a patient with great organic disease. Since that time, I have been present with Mr. Marshall of Greek-street, at the post-mortem inspection of the body of a woman who died suddenly of fright, in consequence of a fire in the next house to that in which she lived, in Crown-street, Soho. We found in that case exactly the same diseases as in Mr. Robinson's patient—viz., fatty degeneration of the heart, and great enlargement of the liver, dis-

placing the viscera of the chest. Dr. Aschendorf has attributed to chloroform the death of a child a year old, from whose face and neck he extirpated a large naevus, which extended from the zygoma to the os hyoides, and from the external auditory meatus to the maxillary fossa. No one else had been willing to undertake its removal. The operation lasted eighteen minutes, and only nine drops of chloroform were used in all. The child died suddenly at the end of the operation. As no chloroform had been applied for eight minutes before death, and then only three drops, it is quite impossible that this agent could have been the cause of the fatal result, and it only seems curious that the operation did not suggest itself to Dr. A., as affording a sufficient explanation of the event.—*Lond. Jour. of Med.*

#### ON THE MANAGEMENT OF WOMEN AFTER THE CESSATION OF MENSTRUATION.

By Dr. E. J. TILT.

THE superabundance of blood and nervous energy after the cessation of the menstrual flow may be safely and effectually kept down by the habitual use of small doses of purgatives; and as these may have to be continued for some length of time, it is best to consult the patient as to what medicine would be best tolerated. The purgative to be used depends upon the constitution of the patient. Perhaps the best is some mild purgative which has been found to agree with the patient. Dr. Tilt continues:—I frequently prescribe the soap-and-aloes pill of the Edinburgh Pharmacopœia, ordering five or ten grains to be taken with the first mouthful of food at dinner. Hæmorrhoidal affections I have never seen them relieved by it; and as I read in Giacomini's Treatise of Materia Medica, my experience on this point is confirmed by that of Avicenne, Stahl, Cullen, and his own, so I think there must be some exaggeration as to the extraordinary property generally ascribed to this valuable drug, which can be associated with hyoscyamus, and is thus said to be less liable to induce piles. Kemp and Hufeland recommend the following powder to be given to those who are advanced in years, and who complain of a tendency to vertigo:—Guaiacum resin, cream of tartar, of each half a drachm, to be taken at night. This, no doubt, will sometimes be found a useful laxative; so will the popular remedy called the Chelsea Pensioner, of which Dr. Paris has given the following formula in his excellent Pharmacologia:—Of guaiacum resin, one drachm; of powdered rhubarb, two drachms; of cream of tartar and of flowers of sulphur, an ounce of each; one nutmeg finely powdered, and the whole made into an electuary with one pound of clarified honey: a large spoonful to be taken at night. I generally administer the flower of sulphur alone, or else to each ounce of it I add a drachm of sesquicarbonate or biborate of soda, and sometimes from five to ten grains of ipecacuanha powder. One to two scruples of these powders, taken at night in a little milk, is generally sufficient to act mildly on the bowels, and I consider such combinations as very valuable when a continued action is required. I feel obliged to class sulphur amongst purgative remedies because such is its visible action, but I believe that it owes its chief value, in diseases of cessation, to another action, much more difficult to understand, and which has long rendered it so valuable both in hæmorrhoidal affections, where there is an undue activity of the intestinal capillaries, and in skin diseases marked by a morbid activity of the cutaneous capillaries. Whether sulphur cures by acting on the nerves or on the bloodvessels, or by modifying the composition of the blood itself, is difficult to tell, but does certainly cure the diseases I have enumerated. It forms part of many popular remedies for the infirmities of old age, was recommended by Hufeland, and is lauded by Dr. Day in his work on the Diseases of Old Age; but its utility is not generally known in all derangements of the menstrual function, at whatever period of life they may occur, and particularly at the change of life, where, if required, its action may be continued with impunity for months and years.—*Prov. Med. and Sur. Jour.*

#### EXPERIMENTS FOR ASCERTAINING THE PURITY OF SULPHATE OF QUININE.

By M. GUIBOUT.

IN the course of the year 1850, the Medical Jury of the Northern Department, caused four bottles of sulphate of quinine to be seized which had been delivered at the Pharmacie of the Hospitals of Valenciennes; they stated it to contain a certain quantity of salicine. This sulphate bore the seal of a Paris manufacturer, and the School of Pharmacy here were desired to take specimens of it, and submit them to a chemical examination. The result of this examination was, that the sulphate, several bottles of which had been indiscriminately taken from a very great number, not only was found free from salicine and all other substances foreign to cinchonins, but furthermore, that it did not contain the smallest portion of cinchonine. The experiments on this occasion having presented a few new facts, we are induced to record them.

1. *Determination of the quantity of water.*—2.5 grammes of sulphate taken from a bottle, the contents of which were thoroughly mixed, were dried in a closet heated by boiling water. The loss was 0.39 grammes, answering to 15.6 per cent. of water, or to seven equivalents and a half. This quantity of water is that which is usually found in the half-effloresced sulphate of commerce.

2. This sulphate does not redden on the addition of concentrated sulphuric acid, and does not contain salicine.

3. When concentrated sulphuric acid is added, it assumes a very pale greenish yellow colour, which might be supposed to indicate the presence of a small quantity of phloridzine. But as it does not undergo the least colouration when exposed under a receiver to the vapour of liquid ammonia, it is evident that that substance is not present.

4. This sulphate is very slightly soluble in cold spirit, containing 90 per cent. of alcohol; but it dissolves completely and very rapidly on the application of moderate heat. This experiment shows that it contains neither gum, fecula, sulphate of lime, sugar of milk, nor even sugar.

5. This sulphate is completely soluble with heat in water, acidulated with sulphuric acid; it therefore contains neither fatty acid nor sub-resin.

6. *Test by baryta.*—In order to ascertain if the sulphate of quinine contains sugar, salicine, phloridzine, mannite, &c., and to effect the separation one from the other of these substances, the addition of baryta water to the dissolved sulphate has been recommended; but whether we operate thus, or triturate the pulverized sulphate with an excess of baryta water during some length of time, we can only succeed in producing a sub-sulphate of quinine, sensibly soluble in cold water, and partaking in common with quinine itself, of the property of becoming insoluble on the application of heat. In order to obtain the entire decomposition of the sulphate, it must be heated for half an hour with an excess of baryta water; left to cool; a current of carbonic acid passed through the liquor, and then filtered. If the sulphate of quinine be pure the liquor should contain nothing, at least it has been so considered; but it does retain in solution a rather considerable quantity of quinine, which only becomes separated when the water which serves as a water bath enters into ebullition. We discovered this fact when operating on the sulphate of quinine submitted to us for examination, and we have furthermore proved, that a very concentrated liquor, deprived of nearly the whole of the quinine which it contained, did not indicate the presence of sugar, mannite, salicine, or phloridzine. Unto the very last we only obtained quinine, which was entirely convertible into sulphate, and without any colouration on the suitable addition of sulphuric acid.

7. *To detect the presence of sulphate of cinchonine.*—With this view M. Liebig has recommended the following process: 1 gramme of sulphate of quinine is to be triturated in a porcelain mortar with 60 grammes of liquid ammonia; the whole poured into a bottle, and 60 grammes of sulphuric ether added. It is to be agitated several times, at intervals, and then left to repose. The quinine dissolves in the ether, but the cinchonine, if there be any, remains insoluble, floating between the two layers of ethereal and ammoniacal liquid.

This process appeared to us the most simple of all those proposed. But as is also remarked by our colleague M. O. Henry, the cinchonine is not completely insoluble in ether, and ammonia, employed in so great an excess, may also dissolve a certain quantity of alkaloid, we adopted the following modification of the process:—2.5 grammes of sulphate of

quinine, taken from a perfect mixture of the sulphate contained in a bottle of 30 grammes, were introduced into a bottle with 15 grammes of liquid ammonia. After having thoroughly agitated the mixture, it was allowed to stand for twenty-four hours, in order to be certain of the entire decomposition of the sulphate. It was then heated in a water bath, so as to almost entirely volatilize the excess of ammonia; then left to cool, and 30 grammes of pure ether added. By agitation, the quinine rapidly and entirely dissolved, so that two superposed transparent liquids were in the bottle—namely, the water containing the sulphate of ammonia and the ether containing the quinine. This experiment, which is very accurate, proved to us that the sulphate of quinine submitted to our examination did not contain sulphate of cinchonine. To assure ourselves of the value of this process, we repeated it, adding to two grammes of pure sulphate of quinine one decigramme of sulphate of cinchonine. The ether dissolved the quinine as readily as in the preceding experiment, but there remained an insoluble cinchonine residue, partly adhering to the inner surface of the bottle, and partly in the form of an opaque layer, between the two liquids. This insoluble residue was so voluminous and apparent that a fourth or fifth part of sulphate of cinchonine added, would by this means be easily detected. It is furthermore very easy to obtain the cinchonine, and ascertain its weight, by removing the ether by means of a tube, replacing it by fresh ether, which again is to be removed; then collecting the residue on a small weighed filter, washing the bottle and the filter with distilled water, &c.

Besides several entire bottles of sulphate of quinine, weighed, and bearing the seal of the manufacturer, whose sulphate it was said was of great purity, the Professors of the School also examined a sample of the same salt taken from an open jar used for retail purposes. This salt did not reddens on the addition of sulphuric acid, and dissolved completely in acidulated water. Treated with boiling alcohol, it left an insoluble residue, not very considerable, which was sulphate of lime. Treated with ammonia and ether in the manner we have above described, the solution of the quinine was almost instantaneous, but there remained (in two grammes of the sulphate employed) between the two liquids, a white and opaque film, which was probably cinchonine, the weight of which was but slightly perceptible in the test balance. There also remained at the bottom of the aqueous liquid a grayish and flocculent deposit of sulphate of lime; but the quantities of the two sulphates of cinchonine and of lime indicated by these tests were so minute, that they could not be considered as the result of a fraudulent addition.—*Journal de Pharmacie and Pharmaceutical Journal.*

## GOUTY INFLAMMATION OF THE STRUCTURES OF THE EAR.

By WM. HARVEY, Esq., M.R.C.S.

GOUTY inflammation of the ear, whether it attacks the external or internal part of the ear, always appertains to the uncertain class of suspicious diseases; for if the patient be really reestablished in health, still he is never secure from relapses. The prognosis is most favourable when the inflammation is seated in the external part of the ear, when the individual is young and strong, and is in such a state that everything necessary for his cure can be applied. It is less favourable if the patient is very weak and sensitive, is advanced in years, or of a cachectic habit, and has been frequently exposed to attacks of gout; changes have then taken place in the meatus and membrana tympani, whereby the nutrition of these parts, as well as the function of hearing, becomes injured. The internal gouty inflammation of the ear yields an unfavourable prognosis, for in it such disturbances and total changes of the tissues and structures take place, are followed, if not by complete deafness, at least by an extreme degree of hardness of hearing.

In the treatment of gouty inflammation of the ear, the first care of the surgeon should be to see that the patient is withdrawn from the noxious influences which first occasioned the disease, and that the inflammation is checked. In order to attain this end, every action of cold damp air, and, above all, of everything which might promote or add to the congestion of blood in the head and ears, must be avoided; on the contrary, living in a dry temperate air, spare diet, food easy of digestion, and perfect rest of mind and body, are recommended. It is easy to see that in the commencement the so-called anti-arthritis, which in general belong to the class of the exciting medicines, are not applicable, and that only an appropriate antiphlogistic mode of treatment is admissible. In this case one must be directed partly by the age and con-

stitution of the patient, partly by the seat and degree of the inflammation, as well as by the violence of the accompanying fever. If the inflammation of the meatus be slight, no blood-letting is required, but if it present a violent character in all its phenomena, it should be reduced by local bloodletting—by means of leeches placed around the ear. But if the inflammation has seized on the internal ear, and has attained considerable intensity, then, in case the patient is strong, plethoric, and not advanced in years, the practitioner may employ a proportionately copious venesection. He should, according to the violence of the local symptoms, place a greater or less number of leeches around the ear, and apply the cupping-glasses to the nape of the neck, to the shoulders, and the spine. In weak and elderly individuals, and where the inflammation is not violent, or is chronic, leeches or cupping-glasses suffice. Internally, we should prescribe mild antiphlogistic aperients in such cases, so as to produce copious evacuations by stool, and a derivation from the head and ear as quickly as possible. After the inflammation has been moderated, it is very easy to remove it entirely from the ear. Together with careful attention to the bowels, remedies which moderately promote the cutaneous transpiration are subservient to this end; accordingly, I have found the continued administration of guaiacum, combined with alkalies and colchicum, or ammonia, the most efficient remedies. At the same time we should not neglect repeatedly to employ cutaneous irritants which derive powerfully—namely, acrid foot-baths, sinapisms, and blistering plasters to the nape of the neck, and to the shoulders. Should the inflammation of the ear be a consequence of a suddenly suppressed action in any joint whatever, we should apply here a cutaneous irritant, which may act rapidly. In less urgent cases we may employ frictions of croton oil, or tartar emetic ointment, over the region of the mastoid process, and on the nape of the neck; blisters to be kept open, issues on the upper part of the arm, and setons in the neck. If, by the internal treatment, the inflammation is crushed, and one has now to do only with the after-consequences of the same, then we should direct our efforts against the gouty disposition, and seek to ward off relapses. We should, accordingly, in the first place, prescribe an appropriate dietetic line of conduct, recommend the use of food simple and easy of digestion, forbid strong beer, acid and heavy wines, liquors, and other such drinks, as well as all heating, flatulent, fat, salted, and highly-seasoned food. The patient should take sufficient bodily exercise, not tarry too long in bed, clothe himself sufficiently warm in order to protect himself from catching cold, cover the head with a warm cap, and use friction carefully over his body.

In order to remove the disturbance in digestion, the acid formation of mucus, obstruction, &c., those resolvent and bitter remedies so frequently celebrated in gout, will be found serviceable, as the infusions, decoctions, and extracts of taraxacum. Several aperient and diuretic mineral waters act very beneficially, more especially in the case of congestions in the head. To act on the lymphatic system and the excretions generally, sulphur will be found useful. With respect to the local treatment of arthritic inflammation of the ear, whether the internal or external parts of the ear be affected, nothing further is to be done at first except to cover the ear and the entire side of the head affected with warm dry cloths and the like. Every moist application is carefully to be avoided, neither the lesser nor the greater degree of arthritic inflammation of the ear will admit of any such. In order to remove the morbid sensibility of the nerves of the ear, we may rub into the parts surrounding the ear the fluid ointment mixed with opium or extract of belladonna, or allow a solution of one grain of morphia in half an ounce of olive oil to be dropped in. In case of abscess forming in the meatus, and suppuration in the cavity of the tympanum, much relief will be afforded by a free liberation of the integuments covering the mastoid process, and kept discharging by a sponge tent in the wound for some time after; soothing and anodyne vapour and poultices are to be employed. Should a purulent discharge have established itself, the meatus must be carefully dried and covered with a compress, or the like. Obstinate ulcers in the meatus should be treated with the tinct. opii camph., and even with lapis infernalis. Should any affection of the mucous membrane set in, it is to be treated in the same way as in the case of the common catarrhal otitis. In order once more to awaken the sensibility of the ear, which has been changed by inflammation with respect to impressions coming from without, benefit will be derived from frictions with the volatile liniment, opodeldoo, oleum cajeput, &c.—*Prov. Med. and Sur. Jour.*

## REVIEWS AND NOTICES OF BOOKS.

NOTES ON LUNATIC ASYLUMS IN GERMANY AND OTHER PARTS OF EUROPE. By W. F. CUMMING, M.D., late Bengal Medical Establishment. London. 1852. pp. 82.

THE result of Dr. Cumming's interesting researches does not tend to prove the truth of the notion that they order these things better out of England. Beginning at Hamburgh, where he found the condition of the lunatic asylum "a disgrace to a city calling itself free," the doctor did not find matters much better at Berlin. Some improvement was noticeable in Saxony and Silesia, but the asylum which Dr. Cumming seems to have most approved of was that of Prague. On all these institutions, as well as on those of Halle and Siegburg, the observations of Dr. Cumming will be found full of interest; but perhaps the most remarkable contribution he has made to the information of the British medical public will be found in his account of the Lunatic Community of Gheel, in Belgium. Our readers will thank us for the following extracts from his description of this strange village:—

"The village is situated about thirty-five miles from Antwerp, in the department of the Deux Nêthes, and is reached by diligence in about seven hours. There are two considerable and populous towns, Lierre and Herenthal, on the route, but the country generally is flat, barren, and uninteresting, being covered for the most part with heath and fir, with here and there some tracts of cultivation. The village is approached through a straight formal avenue of poplars, about three miles in length, and consists chiefly of a 'place,' and one long wide street, having a large church at each end, the one called St. Dymna (written Nymna by Esquirol), the other St. Amans. The peculiarity of Gheel consists in there being no large building for the reception of the lunatics, but in their being boarded in the village or in the farm-houses throughout the commune. Although not furnished with introductions, I was politely received by Mr. Vygen, the Commissary of Police and Directeur des Aliénés; and by Dr. Parigot, the principal physician, who holds the appointment of superintendent of the lunatics of the department of Brussels, 366 in number.

On Sunday I attended high mass in the church, which was crowded with lunatics and peasants, all mingling together. One woman entered with chains round her ankles, making a clanking noise as she walked up the aisle; and Dr. Parigot, who accompanied me, informed me that the chains were applied in her case as a drag to restrain her wandering propensities. The commune of Gheel has a population of 10,000 souls, of whom 1000 are lunatics. During the three days of my stay, I visited, in company with Dr. Parigot, a great number of the cottages in which the lunatics are boarded, both in the village and surrounding country. Indeed, there is scarcely a house that does not harbour one, two, or three patients, who, for the most part, are in full possession of liberty. A great proportion are employed in cultivating the soil, while some assist in household work, others tend the cows, dress the little gardens, or even nurse the children of their hosts. I saw several female lunatics with infants in their arms, whom they were fondly caressing.

The minimum board for each lunatic is 200 francs per annum, and it is remarkable that for so small a consideration any family should risk the disturbance of its peace by admitting an insane stranger to share its fireside. But it appears that the villagers of Gheel have a peculiar vocation for the treatment of the insane, among whom, from infancy, they have been accustomed to live. Many of the better class of houses are tidy and clean, and even those receiving the smallest rate of board are not without an air of humble comfort.

A committee of inspection, consisting of a physician, the commissary of police, and the burgomaster, has power to visit the cottages, to inquire into the treatment of the patients, and to punish instances of ill usage, which, however, according to Dr. Parigot's experience, are extremely rare. On the contrary, the lunatic is treated with peculiar indulgence; the snugest corner by the fireside is set apart for his chair, and he is in every respect looked upon as a member of the family.

During my walks I saw only two patients under restraint—namely, two women who were chained by the ankles; the one, as already mentioned, in the church, and the other a handsome young girl labouring under erotomania. Admitting the necessity of preventing escape, we may still regret that less questionable means than the use of iron fetters are not resorted to.

Since 1842, when the burgomaster was killed by a lunatic, no instance of any serious accident to the villagers has occurred; and within the last three years there have been only two cases of suicide. I should remark, however, that patients known to labour under strongly-marked homicidal or suicidal mania are not received at Gheel. According to Dr. Parigot, cases of illicit intercourse between the sexes are of very rare occurrence.

There are several 'estaminets' in the village, whither many of the lunatics resort to enjoy their pipe and glass of beer, and play at billiards. Their presence nowhere excites the smallest attention. I met a man hurrying along on Sunday evening in a state of great excitement, flourishing a large cudgel above his head, but no one seemed to notice or molest him."

## MEDICAL REFORM.

WE scarcely expect that our readers will cast an eye over what we write under this head, so utterly fruitless have been all attempts to give effect to any plan having this object in view. We must, however, nevertheless handle the subject after editorial fashion, although it is not one we should select if we consulted our own comforts; for of a surety it is not an agreeable one. To analyse a question involved in such a mass of contradictions, anomalies, and incongruities, would be no easy task under the most favourable circumstances; but to detect the elements which enter into its composition, distracted by conflicting interests, seems impossible. On no one principle can the contending parties agree, on no one rule of practice can they rely; for what suits the purpose of one is adverse to the views of the other. Nothing seems more plain than that a person can be taught to treat disease, that his proficiency therein can be ascertained, and that his right to exercise his faculties in this respect is undeniable; but no two can agree as to how he should be taught, how his proficiency should be tested, or how far his right to practise should be recognized. The course of education to be pursued, the nature of the examination, and the extent of licence to be given, are all matters of debate and the cause of angry collision. The lecturer relies on oral instruction, the author extols written rules, and the practitioner pins his faith on practice; each contending for the exclusive efficacy of his own method; but no umpire can be found to declare their comparative value. All agree that the candidate for a place in our profession should devote a certain length of time to study; they even agree as to the precise period. He shall, they say, be "engaged in the study of his profession for four years," but then comes the practical application of the rule. Four years, says one, means four "sessions" of six months; four months, says another, makes a session, and as "the certificates" can be had in three sessions, it follows that the four years may be represented by this reckoning. Some scrupulous body, however, demurs to this calculation, and here *in limine* is a stumbling-block, and no one to remove it. An education of four years is virtually represented by twelve months' attendance in the schools and

hospitals, and no authority can be found to forbid it, and why? Just because every authority knows that if stringent rules be enforced in any one School or College, another can be found only too happy to relax discipline; and for this monstrous abuse no means of correction exists. At the present moment not less than twenty different bodies grant diplomas, licences, degrees, or certificates, purporting to be qualifications to practise Medicine or Surgery, and of these twenty no two agree as to the education of the student, or adopt any uniformity in their examinations. It was, we are bound to admit, in consequence of this strange state of affairs, that heads of departments of the public service, requiring medical officials, considered it necessary to revise the decisions of the Medical and Surgical Colleges by an examination of their graduates, members, or licentiates, previous to their admission; and not only that, but to prescribe additional branches and periods of study. Nay, more; so lightly do they hold these decisions made under the authority of royal charters and acts of parliament, that they actually assume the right to dispense with them altogether, or to substitute spurious for genuine ones. Thus do the two Poor-law Boards, the Army, the Navy, the Ordnance, and East India Company Medical Boards, assume the right to declare the qualifications of candidates for medical office: *ipso facto* assuming the functions of Licensing Colleges, and thereby increasing the number from twenty to twenty-six. But it does not rest even here, for the very boards of hospitals, dispensaries, and lunatic asylums are found prescribing their qualifications, and deciding that this or that diploma is to be preferred to this or that licence. Nor is this enough; for while this profusion of sources of "medical honours" exist, we find the Board of the Apothecaries' Hall of Dublin endeavouring to obtain currency for its licence to open shop as a medical or surgical qualification, and the Board of Trinity College attempting to utter a sham surgical diploma by way of compensation for the reduced stipends and diminished fees of their medical professors. But it is not to end even here, for we hear that the Senate of QUEEN VICTORIA'S University in Ireland begin to think that they should not lag behind the Board of that of QUEEN BESS, and therefore that they must give their "grads." a "dip.," as the phrase now runs amongst the juveniles. This, however, is but the beginning of an end; for it is obvious that the London University must follow the example of its Dublin sisters, and frank their parchments with a Chirurgical Queen's Head; and we need scarcely say that our friends north of the Tweed will not lose the opportunity of improving one of their staple exports by the manufacture of a few additional patterns. Edinburgh will, doubtless, provide a university surgical diploma to compete with its College of Surgeons, and with Glasgow, where two are given already, and Aberdeen cannot be content with a smaller number. Whether St. Andrew's can live without a similar convenience we cannot tell; or whether Durham University, with a Medical School in Newcastle, can "progress" without the "double qualification." All this may seem very extravagant, and a great exaggeration of the results of the intrigues of a few insignificant persons, but our readers may rely upon it that what we predict is at least probable, and that before many years elapse those who obtained their qualifications at great pecuniary sacrifice and much labour will find themselves nothing but members of a medical mob.

## UNIVERSITY REFORM.

ALTHOUGH we may not have Medical Reform, there is some chance of a University Reform. Commissioners are at work, and so are the claimants for privileges usurped by the few. It will probably be found that Universities are not to be Universities in title only, when the true origin and nature of such institutions come to be understood:—

On the foundation of the Metropolitan University, a pledge was given that its future graduates should possess equal privileges with those so long enjoyed by the ancient English universities. That pledge was only a formal recognition of the fact, that hitherto a large and continually increasing portion of the educated classes of this country had been denied those academical and constitutional rights which Oxford, Cambridge, and Dublin conferred. It was an admission that hitherto a sincere or a professed orthodoxy of creed had been the exclusive test of qualification for university honours. The fundamental laws of Oxford, Cambridge, and Dublin, exact a rigid adherence to that test. A just relief from intolerable disabilities could only be provided by the institution of a new university, based upon the principle of religious toleration; and those who had been hitherto excluded could accept of nothing less for the new university than the discerning liberality of our forefathers had bestowed upon the old. Such is the right, and such the compact, upon which the University of London claims coextensive powers with her elder sisters. Up to this moment the promise of equality is unfulfilled; the graduate of the University of London has nothing but his degree. The substantial accompaniments upon university honours—incorporation and parliamentary representation—are still withheld; but a niggardly instalment of justice has been granted. The time has surely arrived when the University of London should manifest a new stage of development—when it should emerge from the condition of a government executive board, only adapted for the earliest period of its existence, to its destined perfection. That the time has arrived is declared by the fact, that so long as four years ago the number of the graduates had reached the minimum indicated by the senate as that which would render it expedient to remodel the university. That the graduates are qualified, not only by number, but by social and scientific position, intelligence, and every other reasonable claim, is notorious. That they are further qualified by a vivid sense of responsibility, by a thorough comprehension of their position as the instruments of a great educational movement; and lastly, by a resolute determination to achieve those great measures of reform which would render their university metropolitan in reality as well as in name, is abundantly testified. During the last four years they have held a succession of general meetings, all attended by such numbers, and animated by such continued zeal and singleness of purpose, as have rarely been known in the history of public movements. They have further evinced their public spirit by liberal subscriptions, and, by means of their committees, they have prosecuted their claims with the senate and the secretaries of state with temperate firmness and unflagging perseverance. In the year 1840, when the infant institution scarcely reckoned a score of graduates, the senate took into consideration the question of the future incorporation of the graduates with a definite share in the government. The committee of the senate decided that when there should be three hundred graduates of three years' standing, it would be expedient to constitute them, and all future graduates of similar standing, the electoral body. By this vote the senate decided two things—first, by the consideration of the question, they proved that the then, and present constitution, was only of a temporary character, and that they to whom had been entrusted the provisional direction of the new university had felt it to be their first duty to settle the basis of its permanent organization; and secondly, they fixed the exact period when the permanent form of organization should be inaugurated. The principle and the time are equally set at rest. Seven hundred graduates now demand to be invested with those rights which the senate have declared three hundred to be competent to exercise. Can the issue be doubtful? Such, then, is the position of the first measure—academical incorporation. The second measure—parliamentary representation, a privilege for which the highest qualification is intellectual superiority, merits special attention. We must therefore reserve it for another opportunity.—*Lancet*.

## MEDICAL QUALIFICATIONS IN ENGLAND.

SOME estimate may be formed of the utter degradation of Medicine and Surgery as a profession in England by a perusal of the advertisements for situations and assistants. In no other department of trade could anything like the following be found. Here are the qualifications required and tendered :—

## HEIGHT AND WEIGHT.

Wanted a young gentleman, about 24 years of age, legally qualified, to assist a medical man in country practice, who has been accustomed to horse exercise. *Height and weight* required.

## WHISKERS.

TO MEDICAL ASSISTANTS.—Wanted by a country medical firm, a gentleman to dispense and attend midwifery, and occasionally to visit. He must be *unmarried, whiskered*, and not under 28 or 30 years of age in *appearance*. The diplomas of the London College and Hall, or at least the latter, will be essential. The duties are light. Salary, forty guineas the first year, with board, lodging, and washing, and an advance of five guineas the second year. Personal application to be made (at four p.m. daily, until April 29th) to J. Love, Esq., 12, Brook-street, Grosvenor-square; or post-paid letters to K. W. T., care of same gentleman.

## RELIGION.

To be disposed of, a small practice in a populous, thriving village. Two-thirds of the population, including the most opulent, being dissenters, a dissenting practitioner would be sure of success.

Even the absence of qualification appears to be a passport to employment :—

Wanted, by a gentleman, *unqualified*, a situation as dispensing and visiting assistant. He is competent to attend midwifery, &c.

We hope that the advertisement upon which we advertised a fortnight ago, from one of this class of traders, intimating that “no Irish” need apply, is superfluous as regards these temptations. Struggling for existence, as many are amongst us, such “qualifications” as those above required are not relied on.

TO CORRESPONDENTS.—The question respecting Inquest Law requiring inquiry, we must postpone our answer to our next number. The note respecting the arrears due to Dispensary Surgeons by Treasurers of Grand Juries, shall also receive attention.

## THE MEDICAL CHARITIES BILL.

## TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Dr. Smith, in his letter which appears in the last number of the MEDICAL PRESS, states that “the majority of the medical profession in Ireland have mainly themselves to blame for many of the evils they now complain of.” I, for one, do not agree with Dr. Smith in this self-accusation. We have not ourselves to blame that things are as they are. But we have to blame the late government, Sir W. Somerville in particular, and, some say, other parties. The truth is, we have been cajoled, deceived, betrayed, and, it is whispered, sold. For fourteen years we had successfully resisted the machinations of the poor-law officials; and at length we have only fallen through the artful abandonment of the first Medical Charities Bill of Sir Wm. Somerville (which contained some protection for the interests of the sick poor and of our profession), and the like artfully sudden introduction, and passing, without a moment's time for reflection, of the long impending poor-law bill, in all its faultiness. That manœuvre, in the teeth of Sir W. Somerville's specious professions, has handed over the sick poor and their medical attendants, bound hand and foot, to the tender mercies of the Poor-law Commissioners and the Poor-law Guardians; the latter the natural enemies of the poor and of the medical profession.

But we shall have ourselves to blame, if we, even under the bill, tamely submit to extravagant exactions, and to be deprived of our services,—of our own labour, and of the

labour of our horses and servants, without reasonable remuneration. How, then, are we to resist these exactions, and protect ourselves from injustice? Simply by an efficient organization. Not by general meetings in Dublin, whose failure Dr. Smith deplures, but by independent county associations in correspondence with each other. It is futile to think that any great number of the profession would or could assemble in Dublin, except on some rare and extraordinary occasion. To attend a meeting there would require a practitioner, residing at any great distance, to absent himself three days from his business, and expend in hard cash some two or three pounds. These are sacrifices not now to be expected from a man having a batch of visiting tickets every morning on his breakfast table, and whose family, his horse, and servant have to vegetate on £60 a year.

The profession, then, can be effectually organized only by the creation of county associations, and it so happens that a staff is already in existence that can easily promote their development. The estimable Chairman and Secretary of the Committee of Medical Attendants, &c., have but to issue a brief circular to their local secretaries throughout the country, to call a meeting of the profession in each county for this purpose, and the thing is done.

Of course, each county association should have a chairman, secretary, and other officers. These, in each province, would form a provincial committee. And on important occasions, they could assemble in Dublin as a national committee. In this way, full attendance and representation at the provincial and national meetings would be ensured; for each of these officers would feel himself bound, in his official capacity, to attend. And even in the intervals of these meetings, the county associations, by corresponding with each other, could act in unison, and with a weight that would compel respect.—Yours truly,

ONE OF THE DISPENSARY MEDICAL OFFICERS.

We of course have the name of the writer of this letter, and can vouch for his ability to deal with the subject. The proposed organization of local associations we ourselves suggested some time ago.

## THE INSURANCE COMPANIES.

## TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—Having seen by your journal that your attention has been drawn to the subject of non-payment of medical men by insurance companies, I think it but justice, not only to myself as a medical agent, but also to the respectable company which I represent, to state that in all cases where I ask for a medical opinion or certificate, I enclose a fee of £1 1s., as you will perceive by the enclosed printed circular, which states as follows :—

“You will receive a fee of one guinea from the society when the inquiry is concluded, and whether the life proposed be accepted or not.”

Hoping that you will give insertion to this in your next publication, I have the honour to be your very obedient servant,

GEORGE B. OWENS, M.D..

Agent to the Medical, Legal, and General Mutual Life Assurance Company.

Dublin, 25, Kildare-street, May 2, 1852.

## TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Having read Dr. Robinson's very proper letter from Ballibay, which appeared in yesterday's PRESS, relative to the Clerical, Medical, and General Life Assurance Society, who “never pay a fee to the referee of the party assuring,” I think it just to place in contrast thereto, a company whose title being somewhat similar, might, by a person unacquainted with the several offices, be confounded with that of which he writes; permit me therefore to say, that the Medical, Legal, and General Mutual Life Assurance Society of 126, Strand, London, and which has numerous Irish agencies, being chiefly under the direction of eminent medical and legal practitioners in London, pays a guinea fee to every medical practitioner whose opinion is required by the company. I understand, likewise, that all the transactions of this society are characteristic of the honourable feelings to be expected on the part of such highly respectable directors.—Yours, &c.,

April 29, 1852.

A SUBSCRIBER.

## THE LONDON COLLEGE OF PHYSICIANS.

I OBSERVE that in your editorial remarks on the proposed new charter of the Royal College of Physicians you think it right to depreciate the professional position of the extra-urban licentiates of the college. It would appear as if it were necessary always to have some professional pariahs to be soundly abused. Formerly, the licentiates and "Scotch doctors" were the pariahs, now the class of statute English physicians occupy that unpleasant position. It may interest you and your readers to know that the so-called extra-licentiates are not *extra* in any sense of the word, inasmuch as they are the only legally qualified physicians in England and Wales beyond the municipal boundary of the metropolis, except graduates of Oxford and Cambridge, and are principally graduates of various universities, as Cambridge, Dublin, Edinburgh, and the other Scottish universities, and as Paris, Berlin, and other foreign universities. Amongst them are also un-graduated physicians, who have formerly been general practitioners, and who have preferred the college diploma to that of St. Andrew's or Aberdeen, and for which, as Englishmen, they cannot be reasonably blamed. There are also a few general practitioners in the body, but not in a larger proportion than amongst the Edinburgh or Scottish graduates generally; and they have this advantage over the latter, that although not in the modern sense of the term physicians, they have a perfectly legal right to practise both pharmacy and surgery. These would not of course seek to enter the proposed new college until they had changed their mode of practice, as they would obviously be ineligible.

I observe that you object to the "extra-licentiates" commingling with the *sans pur* of the licentiates on two grounds—first, because their "examination seven years ago was a mere farce;" secondly, because they have paid much less hard cash for their diploma. I do not know that there is any reason to doubt (on these grounds) their legal right to the diploma in their possession, and their legal position is, that they are English physicians, consequently entitled to all the privileges and immunities which their legal position gives them. These, I can assert with some confidence, they will not give up, whatever opinion may be entertained as to the character of the examination they have undergone. They sought the diploma for its legal value, and that they will insist upon. If, however, it be thought advisable to inquire into the conduct of examining boards, previously to any measure of reform being entertained, the inquiry must be general, and will doubtless reveal an edifying array of "farces." The nature of the examination for the extra-urban licence has been already inquired into by a committee of the House of Commons, of which Mr. Wakley was a member; and I think, after the derogatory remarks you have made, it will only be fair to insert the result. On the 14th of June, 1847, Dr. F. Hawkins, the Registrar of the College, was examined as follows (I extract from the Minutes of Evidence), in the presence of Mr. Wakley:—

"1041. Sir R. Inglis—Do you attend the examinations before the censors, and also before the elects? I attend both.

1042. Will you state what is the relative difficulty of those two examinations, as far as you can appreciate them? Some years ago, the examination instituted by the elects was almost entirely a practical one, because, as I endeavoured to explain to the committee on the former day, the extra-licence was scarcely demanded, except by practitioners of an advanced age, and the auxiliary sciences and preliminary education were, therefore, less entered into by the elects than by the censors, who were to examine younger men. Then, when the demand for the extra-licence began to increase, the elects slowly—indeed, not quite in time to meet the altered state of circumstances—but gradually, raised their examination nearer and nearer to a similarity to the examinations instituted by the censors, and within the last twelve months the examination by the elects has been precisely the same as the examination by the censors."

Dr. F. Hawkins stated all this on his honour, in the presence of Mr. Wakley, on the 14th of June, 1847. Well, then, to what does your term "farce" apply—to the period when the examination was "almost entirely a practical one," or to the period subsequent to 1846, since when it has been "precisely the same" as for the intra-urban licence? I apprehend that when parliament enters upon the discussion of

the college charter, it will be difficult in the face of this evidence, taken by its own committee, to show cause for degrading and depriving the extra-urban licentiates in so revolutionary a style as you suggest.

Next, as to the money payment. The College of Physicians, like the Apothecaries' Hall, is a London guild, and requires admission payments for the right to enjoy its privileges. The extra-urban licentiates enjoying none of these privileges, they have no right to enter the college any more than a stranger—no right to practise within its jurisdiction any more than a quack. The college cannot deprive them of their diploma, cannot control them in any way: they are absolutely an independent body. When they come within the jurisdiction of the college, and within reach of its privileges, they will be quite ready, I doubt not, to "make their due payments." In the rules of the Apothecaries' Company we have an exact precedent. The country licence costs six guineas, the town licence ten; but the country licentiate can practise in town without further examination by an additional payment of four guineas, or two-thirds additional. Permit me to apply this precedent to the cost of the college licences. The extra-urban licence costs £24 18s.; add two-thirds, or £16 12s., and the intra-urban licence should be £41 10s. Now, exclusive of the stamp duty (from which the extra-urban diploma is exempt by law), the college payment is £41 17s., so that the actual amount of the money grievance is 7s., pocketed, probably, by the beadle.

I hope these remarks will be received as they are meant to be—explanatory and conciliatory. My attention having been directed to your injurious remarks by members of the body to which I am honorary secretary, I felt I could not do less than communicate with you.—*Letter of Dr. Laycock to the Editor of the Lancet.*

## MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

Dr. J. F. DUNCAN, the interim Treasurer, thankfully acknowledges the receipt of the following sums since the last return:

Dr. Macdonnell, additional donation	...	£20	0	0	
Dr. Martin, Portlaw, donation	...	...	0	10	0
Do., subscription	...	...	0	10	0
Dr. C. Fleming, Molesworth-street, do.	...	...	1	1	0
Dr. Hart, Charlemont-street, do.	...	...	1	0	0
V. W. Russell, Esq., Limerick, do.	...	...	1	0	0
Dr. Bernard, Dundrum, do.	...	...	1	0	0
Dr. G. A. Kennedy, Talbot-street	...	...	1	1	0
Dr. Cardiff, Wexford	...	...	1	1	0
Dr. Thomas Brady, Gardiner-street	...	...	1	1	0
Dr. D. Griffin, Limerick	...	...	1	0	0
Dr. Corbet, Cork	...	...	1	0	0

Additional contributions are earnestly solicited, as the sum available for distribution, as yet received, is nearly £100 short of what it was last year.

Dublin, 19, Gardiner's-place, May 2, 1852.

APPOINTMENT.—Dr. Robert J. Crane has been appointed Surgeon to the Wexford Dispensary.

M. W. HANLON, M.B.

**SCHOOL OF SURGERY.****ROYAL COLLEGE OF SURGEONS IN IRELAND.**

THE Summer Courses of Lectures commenced on Monday, the 26th of April, when Lectures on the following subjects were delivered, in accordance with the regulation of the Council of the College:—

Materia Medica	...	...	Dr. Williams.
Medical Jurisprudence	...	...	Dr. Geoghegan.
Practical Chemistry	...	...	Dr. Barker.
Botany	...	...	Dr. A. Mitchell.

Examinations will be held, and Premiums awarded to the successful Candidates, at the termination of the Session.

**CITY OF DUBLIN HOSPITAL.****SUMMER SESSION.**

THE Clinical Lectures and other forms of Instruction commenced in this Hospital on the 26th of April. By a recent Ordinance of the College of Surgeons, separate Certificates of Hospital Attendance, during the SUMMER SESSION, are required.

**DISEASES OF THE EYE.****SUMMER SESSION.**

**DOCTOR JACOB** will commence his Lectures on DISEASES of the EYE, in the City of Dublin Hospital, on Monday, the 17th of May, and will continue them during the SUMMER SESSION, so as to form a complete Course of OPHTHALMIC SURGERY.

**MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.**

THE Annual Distribution of the Funds at the disposal of the Society will take place on the first Monday in June.

Applications for assistance must be made by printed forms, to be obtained from the Honorary Secretaries, and must be sent in to the Branch Associations before the 6th of May, or to the Parent Society before the 10th of May.

Branches are established in the principal towns of Ireland, and with Honorary Secretaries, as follows:—

Armagh, Dr. Colvan; Belfast, Dr. Stewart; Cork, Dr. Lloyd; Newry, Dr. Erskine; Waterford, Dr. Carroll.

The applications are to be forwarded to the Secretary of the nearest Branch, if any be near, or to the Secretaries of the Parent Society in Dublin.

Subscribers to the Parent Society are requested to send in their contributions as soon as possible to the Treasurer, Dr. Duncan, 19, Gardiner's-place, Dublin; and subscribers to the Branch Associations, to the Local Treasurers respectively.

By Order,

WM. KINGSLEY,

CHAS. BENSON,

Hon. Secs. Parent Society.

Royal College of Surgeons, Dublin, April, 1852.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

*Superior Dissecting Instruments well worth the inspection of the Student.*

**THE COMPOUNDING DEPARTMENT AT****G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Just published, 8vo, pp. 96, price 2s. 6d.,

**A TREATISE ON CATARACT;**

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By **ARTHUR JACOB, M.D., F.R.C.S.,**

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

#### SURGICAL OPERATIONS FOR RETENTION OF URINE.

By Mr. Cock.

THE author first dwells upon the difficulties which surround the question of what course should be pursued in those cases where an old chronic indurated stricture, recently closed by inflammation and congestion, defies all attempts to pass a catheter, and upon the failure which frequently attends the attempts of the surgeon to relieve such cases by the introduction of sounds, catheters, or bougies. He points out the three modes to which recourse may be had, when the urgency of the symptoms renders some decided interference necessary. First, that of forced catheterism; second, that of opening the urethra in the perineum behind the stricture; and third, that of puncture of the bladder. There is nothing new in either of these measures for relieving retention. They may each possess certain advantages, and the circumstances of the case, and the condition in which we may be placed, may incline us to the adoption of either the one or the other. They have all their drawbacks; but on the whole, the author is disposed to believe that the bladder may be reached with the smallest amount of pain, with the least risk of present or future danger, and with the greatest prospect of ulterior good, by puncture through the rectum. The first of these operations the author regards as in reality a mode of puncturing the bladder with a blunt instrument, tunnelling through the perineum under cover of the urethra; and he believes that the stricture is, in the majority of such cases, neither forced nor crushed, but that a new passage is made outside the urethra, which may either reënter the urethra, or continue its course through the prostate into the bladder. The urgent symptoms may be thus relieved, but the after condition of the patient is not bettered, and it may be rendered even worse. The second operation, of section of the perineum, the author thinks, is, when dexterously and successfully performed, preferable to forcible catheterism. The urine may be allowed to flow by the new channel,

until the urethra has had time to recover itself from the injuries it may have sustained by previous manipulation, or from the irritation caused by the continual pressure of the contents of the bladder. But unfortunately the difficulties are often so great, in long-standing disease of the perineum, that the urethra cannot be reached, and great mischief, or even death, may result from the protracted operation. The author describes the proposed modification of this practice, called "cure of stricture by division," of which the principle consists in uniting the upper and lower permeable portions of the urethra by the division of the intermediate impermeable portion, and thus restoring the integrity of the canal. This, however, he thinks, is very rarely carried out; and that very often death is caused unmistakably from the injuries sustained during the operation. So convinced is the author, by experience and observation, of the difficulty which frequently attends the operation of opening the urethra behind the stricture, where the landmarks which should guide us are obliterated, that he has of late years abandoned the operation of incising the perineum, with a fixed determination to reach the bladder. In those cases where retention and extravasation render it necessary that an outlet should be afforded to the contents of the bladder through the perineum, he limits himself to making a free incision down to the region where the urethra may be supposed to be situated; and if he cannot then gently introduce a catheter through the wound into the bladder, he does not proceed any farther; and he has generally found that the urine has speedily found its way through the wound. With regard to the third mode of relieving the bladder, by puncture, the author brings forward cases to show puncture by the rectum safe and simple. Forty cases of operation by the rectum are related. In all of these, the operation was entirely successful, so far as the relief and the absence of any ill consequences from it were concerned. Seven deaths occurred, from various causes connected with the previous sufferings of the patients, as diseased kidneys, inflamed bladder, &c. In many cases, the author believes the operation to have materially tended to the restoration of the patient, with a less amount of suffer-

ing, and at the same time more speedily and effectually, than could have been effected in any other way.

Mr. SOLLY concurred in opinion with Mr. Cock, that the operation described in the paper was a most valuable one in certain cases. He (Mr. Solly) had heard Mr. Cock describe it years ago, and had himself since performed it several times with success. He considered that this operation was one of the least dangerous that could be performed in cases of retention of urine from stricture. Cases of course occurred in which cutting down upon the urethra was advisable—as when the stricture was of traumatic origin; but where the canal had been much damaged, and where false passages existed, the operation of puncturing the rectum was the most advisable.

Mr. ARNOTT said, that although he was unable to speak in the same unqualified terms of approbation as the author of the paper and Mr. Solly had done, of the operation of puncturing the bladder through the rectum, he was yet able to add his testimony generally in its favour from a personal experience of five cases in which he had resorted to it. He considered that the Society was indebted to Mr. Cock for having brought the present collection of cases before it. He (Mr. Arnott) had only performed this operation in cases of retention of urine supervening on permanent stricture, when other means of relief had failed. But having witnessed incidentally its advantages in facilitating the subsequent treatment of the stricture which had rendered the operation necessary, he was prepared to receive with favour the suggestion to resort to it occasionally in the treatment of that disease. Before, however, he proceeded further in his remarks on this operation, he wished to observe that he thought Mr. Cock had expressed himself with too much severity with regard to the operation of what was called forcing the stricture, and also in regard to the operation of opening the urethra behind the stricture. Both of these proceedings, properly performed in suitable cases, were justifiable and safe. The operation of forcing a stricture was not so severe a proceeding as puncturing the bladder from the rectum, and it had some advantages. Indeed, if he had the misfortune to suffer from retention of urine as a consequence of stricture, he should, if in the hands of a competent surgeon, prefer that the stricture should be attempted to be forced before any opening should be made in the urethra behind the stricture, or the bladder be punctured through the rectum. What he wished to convey by the operation being “properly performed” was this, that if upon trying to urge the catheter through the stricture, the urethra itself should give way, and be perforated, then that the proceeding should be immediately abandoned. So also with respect to opening the urethra behind the stricture; the best mode was not that usually performed, of cutting from the surface or skin inwards, but by putting the forefinger of the left hand into the anus, so as to depress it; then to introduce the point of a bistoury slightly curved just in front of the anus, and carry it directly inwards so as to strike the membranous part of the urethra; and then holding the instrument outwards, to divide all the superjacent parts. He (Mr. Arnott) had first seen this mode of procedure resorted to by the late Sir Charles Bell twenty years ago, and had frequently since successfully performed it. If in the operation you missed the urethra, then the operation of puncturing the bladder could be resorted to. With reference to the last operation, which had been employed at the Middlesex Hospital, he had not found it so entirely destitute of disadvantage as had Mr. Cock. Of the five cases in which he had employed it, one patient died, and on examination an abscess was found between the bladder and rectum in the track of the canula. Effusion of urine in this situation was a danger to be dreaded, and he had expected that it would have occurred in some of Mr. Cock's cases; and gratified as he was at hearing the short abstracts of some of them read, he should like to look over the details of the whole before he could satisfy himself that the danger was not real. He could, perhaps, illustrate his views with respect to the different operations, by relating a case in which he had per-

formed all of them in the course of a quarter of an hour on the same patient. In 1844, he was called one morning to an officer of Engineers, who had retention of urine from stricture, and who had had a similar attack some years before. The patient was six feet six inches in height, of large frame, and being partially palsied on one side, was very cumbersome to move. An unsuccessful attempt was made to introduce an instrument into the bladder. Large and repeated doses of laudanum, both by the mouth and rectum, were exhibited at short intervals, and a fresh attempt to pass a catheter was made at the end of some hours, but again without success. A small quantity of water had, however, dribbled away. The patient was now purged, cupped in the perineum, &c. On the following day, the quantity of urine passed was not considerable, yet the relief was such as to lead him (Mr. Arnott) to suppose that the difficulty of the case had been got over. On the following morning early, however, he was again summoned to the patient, and found that he had passed no water since the preceding afternoon; the bladder reached half way up to the umbilicus, and he was greatly distressed. The case now admitted of no delay, and he accordingly attempted to force the stricture, but the urethra gave way, and the catheter was at once laid aside. He (Mr. Arnott) explained to the patient's brother, a physician, that he would now endeavour to open the urethra behind the stricture, an operation in which, in these cases, he had generally succeeded; but in the present instance he did not feel so confident, as there had not been much previous suffering from the stricture, or strain upon the parts, so that the urethra, posterior to the stricture, might not be dilated. If he failed in the attempt, he should then puncture the bladder through the rectum. The attempt to lay open the membranous part of the urethra was made in the way already described, but the urethra was not struck. The bladder was then immediately punctured through the rectum. He (Mr. Arnott) saw the patient twice during the day, when the urine was flowing freely through the canula; but the next day he was called to him again, and learnt that on the previous afternoon the canula had got displaced; it was, in fact, out of the bladder; and that no urine had passed either way since. The bladder was now full, and after a short and unsuccessful attempt to pass a catheter by the urethra, the bladder was again punctured through the rectum; the canula was kept in sixteen days, when an instrument was got through the urethra into the bladder; the case did well, and the patient was still living. In one instance it appears that Mr. Cock had failed to reach the bladder in the attempt to puncture it through the rectum, but failure to strike the bladder was not confined to puncture in this situation. Mr. Arnott had twice witnessed, in the hands of a very able surgeon, the bladder missed in the attempt to puncture it above the pubes; in one of these cases, the trocar was reintroduced, and with success; he might add that both cases recovered.

Mr. COULSON said it was clear from the facts detailed in the paper that the operation of puncturing the bladder by the rectum was easy and safe of performance, but he was not equally convinced that the operation ought to be performed in cases like those mentioned by the author. Puncturing the bladder by the rectum for retention had never been very generally resorted to, because it left the condition on which the retention depended untouched. The late Mr. Liston, in his *Operative Surgery*, says that he never performed the operation in question, and spoke in no measured terms of those who had recourse to it. In some of Mr. Cock's cases the catheter had been introduced not long prior to the operation, and he could not understand why it had not been retained in the bladder, and the operation of puncturing dispensed with. In one or more cases there was extravasation of urine, and he (Mr. C.) thought that the free and deep incisions in the perineum which were necessary to give relief to the extravasated urine would also have been a sufficient outlet for the urine from the bladder. Again, the author had recommended the operation on the ground that by the withdrawal of the

urine from the urethra the stricture would yield; but it was delusive to expect this to be the result in all cases. He had punctured the bladder by the rectum in an urgent case of retention, dependent on an impermeable stricture of the urethra; at the end of three or four days the canula slipped out, and retention again occurred. The stricture was in the same position as before the operation, and was then successfully divided by the lancetted stilet. The conclusions which he (Mr. Coulson) arrived at were, that if the smallest instrument, like one of Mr. Syme's staffs, could be introduced through the stricture, it would be better to divide the stricture from without, and thus remove the cause of the complaint. If the stricture was so great that nothing could be introduced through it, then he would prefer passing a grooved staff down to the stricture, making an opening into the perineum beyond the contracted part, passing a strong, straight director with a deep groove in the median line between the urethra and rectum, and passing a straight bistoury some way along the groove, and then cut outwards and upwards towards the staff which had been first introduced. Except, therefore, under the most urgent circumstances, scarcely admitting of the delay requisite for the performance of these operations, he did not think the measure which had been recommended by the author for retention of urine from stricture should be adopted.

Mr. SOLLY observed that Mr. Liston, before his death, altered his opinion as regarded this operation, as he (Mr. Solly) was present when that distinguished surgeon performed it, a few months before he died.

Mr. DE MORGAN said that he had not perused all the cases detailed by Mr. Cock, but they all supported the same views, and showed that the operations did not, as Mr. Coulson had remarked, remove the cause of the retention. In all operations, however, proposed for the relief of stricture, the urine, after a time, passed more or less by the natural passage, similar to what was observed in some cases lately read to the Society of stricture of the colon, in which, some time after an operation had been performed for their relief, the feces began to pass through the intestine, and take their natural course. The operation, therefore, of puncturing the bladder in cases of stricture, was to some extent a curative agent as regarded the obstruction.

Mr. CURLING had given his best attention to the cases which had been briefly detailed in Mr. Cock's paper. As far as he could judge, he had no objection to make to the puncture of the bladder in the instances cited. In the second case, it did not seem quite clear whether the abscess in the perineum existed at the time of the operation or had formed afterwards; but he did not believe that so excellent and experienced a surgeon as Mr. Cock would venture to puncture the bladder by the rectum in a case of retention of urine with perineal abscess. He would relieve the patients by a free opening at the part. Mr. Curling agreed with the author of the paper, that the operation was more free from risk than was generally supposed; and in giving it the preference of forced catheterism, he was quite sure that Mr. Cock, in treating of the latter proceeding, did not object to the perforation of a stricture by the skillful use of the catheter, but to the violence inflicted when the instrument was driven out of the passage, the course of which, in its progress to the bladder, had been so graphically described in the paper. Still he was surprised to find that Mr. Cock had to puncture the bladder in so many instances at the hospital of which he was surgeon. At the London Hospital, cases of retention of urine were of very common occurrence amongst the dissolute population in the neighbourhood, and no less than 146 cases had been admitted in the past year; yet this operation was very rarely performed, and he did not believe the bladder had been punctured a dozen times during the past twelve years. He attributed this to the remarkable success attending the general treatment without instruments, by means well known to the fellows of the Society. After the retention had been relieved in this way, and the local irritation had subsided, the cure of the stricture could then be conducted with as

much advantage as after the bladder had been punctured by the rectum. In the very few cases in which he had found it necessary to operate, he had punctured the bladder above the pubes, which he believed was as simple and as free from danger as the puncture by the rectum.

Mr. GAY, from the experience he had had of the practice of puncturing the bladder from the rectum, could give it his unqualified support, but in a certain class of cases only—viz., those in which spasm and inflammation suddenly supervened in old stricture, and retention, with all its evils, followed. Amongst the cases detailed in Mr. Cock's interesting paper, he had not been able to detect many of this kind. It was now six years ago that he (Mr. Gay) was called to see an old gentleman labouring under the severest symptoms arising from retention. He had suffered from stricture for years; and the day before, in consequence of a debauch and exposure to cold, he found himself unable to pass his urine. Many futile attempts had been made to introduce a catheter, by which the urethra had become seriously lacerated. Hot baths, leeches, and opium, had also been employed; and it was not until the symptoms of constitutional irritation had reached a fearful height that his assistance was called for. Under these circumstances, he thought it unwise to interfere further with the urethra in any part of its course, but to attend to what was infinitely more urgent—viz., the over-distended state of the bladder. Notwithstanding the bad odour into which the operation of puncturing by the rectum had fallen, he (Mr. G.) determined, though not without much anxiety as to the results, to perform the operation. It was followed by great and immediate relief; and a further employment of palliative remedies to the urethra caused the spasm and inflammation to be so far reduced by the following day, that the old gentleman began again to pass his urine by the natural channel. In a few days more he was convalescent, and nothing was heard whatever of the wound of the bladder made in the operation. Mr. Gay thought the state of the urethra, in such cases, and under such a conjunction of circumstances, to be of all others most unfavourable to catheterism; and from the results of this case, and others which had since fallen under his observation, he did not hesitate to recommend the evacuation of the bladder by these means, whenever that viscus might become so distended as to occasion severe constitutional and local irritation. He had punctured the bladder since in four or five other cases; and so convinced was he of the comparative innocence of the procedure, that he had on one occasion had recourse to it three days following, and this without any bad results. The palliative local treatment of these cases appeared to be more successful after the bladder was emptied, than if employed during its distension, and generally resulted in the patient's being able to void his urine in the course of twenty-four or forty-eight hours. With regard to another class of cases, in which Mr. Cock had been in the habit of puncturing the bladder—viz., those of chronic and permeable stricture—he (Mr. Gay) had had no experience; but, with Mr. Coulson and Mr. Arnott, he could not see its utility. It appeared to him that the result of this practice was to add to an old stricture the undesirable complication of a fistulous passage behind it, which could by no means be of any service towards curing the original disease. He was of opinion that judicious catheterism might in these cases accomplish as much as could be expected. Mr. Gay felt that on so important and interesting a subject, every surgeon who had had any experience was bound to communicate it, for the purpose of arriving at some really practicable conclusion; and it was this consideration that had led him to make these remarks.

Mr. HODGSON deprecated the employment of such violence as had been described in the use of the catheter for the relief of retention of urine in cases of organic stricture, but advocated the employment of that instrument under such circumstance in a cautious manner. By very long continued but moderate pressure, the catheter might often be passed, even through long and obstinate strictures; but

great patience and perseverance were requisite both on the part of the patient and operator, who should also possess the tact and knowledge to enable him to guide, with his fingers in the perineum, the point of the instrument in the track of the urethra. In the course of his experience he had never found it necessary to have recourse to tapping the bladder, either per anum or above the pubes, for the relief of retention of urine. With regard to the former of these operations, he did not regard it as quite of that simple and harmless nature that had been represented. In cases of old stricture the bladder was often very much thickened and contracted in its coats, and incapable of much distension. This state would render the operation difficult, and in some instances unsuccessful. There was also danger of wounding the vesiculae seminales. He mentioned an instance in which this was believed to have happened, and the inflammation having extended along the vas deferens produced suppuration of the testicle. In another instance the tube slipped out of the opening in the bladder, and could not be replaced; the patient derived only very little relief from the operation. In his opinion, this operation should only be undertaken by experienced and cautious hands.

Mr. PRESCOTT HEWETT would confine himself in his remarks entirely to the question of operating for retention of urine from stricture. He would at once say that the opinion which he had formed was, that few, very few cases of retention of urine from stricture imperatively demanded an operation for their relief, and he was surprised to find that so many cases of this kind had required an operation in one hospital alone during the last few years. Mr. Curling had stated that in the London Hospital, operations for retention of urine had of late years been of very rare occurrence, but he (Mr. P. Hewett) would go a step further, and say confidently that for the eighteen years during which he had been connected with St. George's Hospital, not a single instance had occurred in which it was found necessary to resort to an operation for the relief of retention of urine from stricture: and yet among the large number of cases of this kind yearly admitted into that hospital, were some of a most severe and urgent character. He had necessarily been obliged to operate upon cases of extravasation from rupture of the urethra with retention, which had been brought into the hospital in that condition; but this was altogether a different matter, and one in which the treatment admitted of no doubt. For many years past, at St. George's, long antecedent to his (Mr. Hewett's) going there, cases of retention of urine from stricture had been treated, when catheterism failed, with opium and the warm bath, and for the last eighteen years, to Mr. P. Hewett's knowledge, as already stated, and for some years more, no single instance had arisen where an operation had been required. On one occasion, and on one alone, had he (Mr. P. Hewett) seen even anything like an approach to an operation. In this case the patient, a man of intemperate habits, had been admitted into St. George's Hospital with retention of urine from stricture, and some false passages which had occurred during the repeated attempts at passing a catheter into the bladder. Another attempt to get an instrument into the bladder was cautiously made by the house-surgeon; but as this failed, a warm bath was ordered, and some laudanum given by the mouth, and under this treatment the patient soon became easier, and then passed a small quantity of water. Shortly afterwards, however, complete retention again recurred; and as no relief appeared to be derived from the treatment, the surgeon of the week was sent for, and another attempt to pass an instrument was again made, but this also proved fruitless. Under these circumstances, as the bladder was getting largely distended, a question arose as to the propriety of tapping this viscus through the rectum; but as the patient, notwithstanding the great distension of the bladder, did not appear to be suffering much, it was ultimately decided that another trial should be made with a full dose of laudanum, two drachms of which were immediately given by the rectum, and within an hour afterwards the patient began once more to pass his water, and gradually emptied

the bladder. Let opium be freely given, and from what he had witnessed, Mr. Hewett had no hesitation in stating that an operation in such cases would be very, very rarely indeed required. In conclusion, Mr. Hewett stated that he had never seen any bad effects arise in these cases from the free administration of opium, notwithstanding that he had in some instances given drachm doses every hour for three or four hours consecutively.

Mr. CHARLES HAWKINS thought that there should be further discussion on the important paper before them, for he was not satisfied that it should go forth to the profession that the Society entertained so favourable a view of the operation advocated by Mr. Cock, as the remarks of the preceding speakers would naturally give rise to. He (Mr. Hawkins) was by no means satisfied that cases of stricture generally required the operation to be resorted to, and he must say he had never heard a paper read in that room which had more astonished and surprised him, detailing as it did, forty cases in which puncture of the bladder had been resorted to, either by the author or his colleagues. Now, he (Mr. Hawkins) had known St. George's Hospital for the last twenty years, and he had never known this operation to be performed there, nor could he learn that it had been resorted to for nearly thirty years. He also knew that surgeons in extensive practice in the west end of London had found it necessary to have recourse to it only about half a dozen times during the long period of forty years; it was therefore to him most extraordinary that so many cases could be got together from one hospital or from the practice of those connected with it. Indeed, until the remarks of Mr. Curling, he (Mr. Hawkins) imagined that the operation must be peculiar to the other end of London, but it appeared, that though well placed for bad cases of stricture, the London Hospital could produce no such number. He had been surprised to hear of the advantages of this operation in cases of spasm, for these were surely not the cases in which Mr. Cock recommended it, for he appeared to confine its use to those old cases of permanent stricture where from constant attacks of retention of urine and its consequences, the kidneys and bladder became diseased, and the life of the patient placed in jeopardy. In such cases, if an operation were required, then that recommended by Mr. Cock, he (Mr. Hawkins) considered the best. He thought, however, that at the present time, when so many plans of treating stricture were being placed before the public, it was most desirable that the Society should not without due consideration, give its sanction to any particular plan. He hoped that the older and more experienced fellows of the Society would express their opinions in reference to this operation; with this view he had addressed the Society. It was not that he did not think that, when an operation for the relief of retention of urine became necessary, that recommended by Mr. Cock was perhaps the one attended with least difficulty and followed by fewer bad consequences than any other, but of the results he could say nothing of his own experience. He could call to mind but one case that had come under his own care in which the bladder was punctured for retention of urine. In that instance, the operation was successfully performed above the pubis. He had been in the habit of passing an instrument for that patient since, without difficulty. Of course he did not allude to cases in which an operation had been performed for the cure of stricture, where the obstruction was permanent—usually from accident—and performed not for the immediate relief of retention of urine. He had assisted at operations in about half a dozen of such cases, the urethra being cut into through the perineum. He had certainly been surprised to hear of the great amount of bad surgery which Mr. Cock appeared to have met with, for such did not commonly come under his (Mr. Hawkins') observation.

Mr. HOLT remarked that he entirely concurred in the observations made by both Mr. Curling and Mr. Hewett, and expressed his surprise at the large number of cases in which Mr. Cock had found it necessary to have recourse to an operation for the relief of retention of urine. He had been engaged for the last ten years in endeavouring

to procure cases of stricture of the worst possible description, and although a large number of cases of retention of urine in all their varieties had come under his notice, yet he had only had recourse to operative procedure in one instance, the operation consisting in opening the membranous portion of the urethra, which formed an elastic tumour behind the stricture, easily detected and easily punctured. If the ordinary palliative treatment were had recourse to, and the first effort failing, no further attempts to pass a catheter were indulged in, in almost every case the urine would in a few hours escape, and in sufficient quantities to obviate all the urgencies of retention, and in a few days (the parts in the intermediate time having become tranquil) a catheter could, in almost every instance, be passed. Were he called upon to perform any operation, he should have no hesitation in preferring, from its simplicity, facility, and the immediate relief it afforded, that recommended by Mr. Cock. He considered the operation of opening the urethra behind the stricture a most hazardous proceeding, and ought only to be had recourse to in cases where the membranous portion of the urethra could be distinctly felt distended by urine. As a proof of this assertion, he might mention a case in which this operation had been attempted by one of the ablest surgeons of the day, a gentleman of vast experience, and who formed one of the heads of the profession. The patient, from continued disease, died the same evening, and the post-mortem examination revealed the urethra completely transfixed, the knife having passed between the bladder and symphysis pubis. Respecting the operation of forced catheterism, he was quite assured Mr. Arnott would not sanction that operation in the common acceptance of the term, or, as recommended by some surgeons, that a catheter should be forced into the bladder *vi et armis*, no matter what strictures intervened. Such a course of proceeding could only be attended with hazardous results, and probably the death of the patient. In conclusion, he felt assured that by patience and proper medical treatment the cases in which it might be necessary to perform any operation would be very limited.

Mr. ARNOTT had hoped, in reference to what had fallen from Mr. Holt, that he had sufficiently guarded himself against the supposition that he was in favour of the operation of forcing a catheter into the bladder. He had expressed his opinion, that the attempt to force a stricture was a proper proceeding in certain cases; and he would again state his meaning, which was this—that with a short silver catheter, gentle but steady pressure should be made on the stricture: if it gave, so much the better; but if the urethra was perforated, as the surgeon would at once be aware of by the sensation communicated to the fingers, and by the bleeding, the catheter should be at once abandoned. He (Mr. Arnott) agreed in the opinions that had been expressed, that the opening of the urethra behind the stricture, in the way in which it was usually performed, by cutting from the skin inwards, was an operation at once difficult, tedious, and uncertain. He had himself experienced these difficulties, and had witnessed them in surgeons of acknowledged eminence. He had also seen the occurrence described by Mr. Holt, of the bladder being opened at the anterior part of its neck. The plan of operating by the curved bistoury was easy of performance and very simple.

Mr. CURLING rose to explain that in the cases in which the bladder had been punctured at the London Hospital, he included cases of retention of urine from enlargement of the prostate gland, which had been injured by instruments, and attended with hæmorrhage into the bladder. He would also mention a remedy for retention from stricture, which was not applicable to persons of debauched habits and broken-down constitutions, but succeeded remarkably well in robust sailors and others. He alluded to the administration of croton oil; as soon as the remedy began to act on the bowels, the patient was able to urinate.

Mr. SOLLY explained that he recommended the operation in cases of permanent stricture, with enlarged prostate, and where great injury had been committed on the urethra. He supposed, from the remarks of the numerous speakers,

that more bad cases of stricture were admitted into the hospitals at the east than at the west end of town.

Mr. N. WARD contended, that the operation was admissible in cases of retention with great distension of the bladder, and if it were done simply for the relief of the intense agony and suffering attendant on that complaint, and for the prevention of paralysis of the organ, on account of its simplicity and safety, as shown by the experience of several hospital surgeons, it might be resorted to.

Mr. CHARLES HAWKINS expressed his surprise that Mr. Cock should have met with so many cases of stricture requiring the performance of such an operation, when so many surgeons longer in practice than himself had not done it once.

Mr. WARD had understood that Mr. C. Hawkins was opposed to the operation altogether in the cases alluded to.

Dr. J. A. WILSON remarked, that if he understood the debate correctly, the operation under discussion was sometimes followed by a fistula, and yet it had been described as simple and safe. He would leave that question for surgeons to settle—how could an operation be either simple or safe if it had such a result?

Mr. Cock in reply, said that the operation in question was recommended by him and others as a means to rescue patients from the effects of retention when all other measures had failed. Some misapprehension appeared to have arisen from the number of cases he had brought forward. If his paper had been read in full, it would have been found that only twenty-four cases were his own, and that the others had been furnished by his friends. It might be supposed that he had resorted to this operation rashly. He had not done so, however, and had employed it only as a last resort, except in cases of old, impervious, hard strictures. The cases detailed had extended over many years, having been selected from an immense number of cases of retention of urine. He did not think such severe cases of impermeable stricture were met with at the west end of the town. He had endeavoured to show that this operation was only to be had recourse to in the severest cases, when every other palliative measure had failed; indeed, he was of opinion that he had used palliatives too long. He had mentioned three modes of proceeding for the relief of retention of urine; the first, by forcible dilatation; the second, by cutting into the urethra between the stricture and prostate, respecting which he explained its deficiencies and dangers, all of which were great, and frequently led to failure; the third, which he had mentioned, without detracting from the utility of the others, being more simple, less painful, and more likely to succeed. Fistula had been spoken of as a drawback; but he (Mr. Cock) had never known of an instance of this, when the permeability of the urethra had been restored. One of the virtues of the operation was obtaining this persistency as a sort of safety-valve, until a free passage per urethram had been secured; there was often some difficulty in securing its patency until the canal of the urethra allowed the urine to flow through it. Some of the cases which had been read would illustrate this point. There is not a fistula through which urine distils; but when the bladder is distended, the impulse to evacuate its contents ensues, and then the urine is discharged in a gush by the rectum, instead of by the urethra; and it is a great comfort to the patient, after enduring the suffering from such a condition of the urinary organs, to be able to discharge the contents of the bladder in a gush. There is one other point which he (Mr. Cock) wished to allude to: it seemed to be denied by Mr. Coulson and by Mr. Gay, that relieving this state of those parts places the strictured portion of the urethra in a better condition for a cure to be effected than previously existed. This denial did not accord with the results of his own experience: every operation by means of which the contents of the bladder can be more freely discharged than was previously the case, must sooner or later place the urinary organs in a better condition; the urethra being relieved from the distress and strain upon it, and consequently the induration and other signs of disease gradually lessen and disappear.—*Lancet*.

# FURTHER OBSERVATIONS ON FRACTURES IN THE VICINITY OF THE ANKLE-JOINT—THE REMOVAL OF SPICULÆ OF BONE, ETC.

By RICHARD G. H. BUTCHER, F.R.C.S.I.,

Examiner on Anatomy and Physiology in the Royal College of Surgeons in Ireland, Surgeon to Mercer's Hospital.

In the *Dublin Quarterly Journal* for this month, we have a continuation of the subject of "Fractures in the vicinity of the Ankle-joint," by Mr. Butcher.

In the *MEDICAL PRESS* for March 17th, we alluded to the first part of the paper, and made extracts from it in reference to the operation of tenotomy as facilitating reduction of the broken bones. In the concluding remarks (the second part of the paper), additional cases are given in support of the mode of practice inculcated, and the following observations on the removal of spiculæ of bone in comminuted fracture:—

## ON THE REMOVAL OF SPICULÆ OF BONE IN COMMINUTED FRACTURE.

As to the time in which the removal of spiculæ of bone is called for in comminuted fracture, the case marked No. 4, in my former paper, offers a good illustration. It is there stated: "The deformity of the leg was very great, the fibula being broken in pieces, from about an inch above the extremity of the malleolus, for at least two inches; one piece in particular, a large one, was forced away from between the upper and lower fragments of the bone, and thrust under the skin on the anterior aspect of the leg, and a little above the joint, thus leaving a great depression, corresponding to the gap in the continuity of the lower part of the shaft of the bone." On the adjustment of the limb every effort was made, consistent with correct practice, to restore to position this detached piece of the fibula, but all to no effect, it projected sharply under the skin, and threatened several times during the treatment to ulcerate its way out; to prevent so unfavourable an occurrence every precaution was adopted; the part was left exposed, the integuments relaxed, and above all, handling of the part was prohibited; my great anxiety being to stay the protrusion of the bone until the broken up parts were consolidated and repaired, and so avert the production of compound fracture, a result greatly to be dreaded, more particularly so in this case, owing to the joint being implicated in the fracture.

On the 28th of December, 1851, the patient referred to was dismissed from the hospital, with the broken leg cured; and with instructions to return immediately, if the projecting piece of bone occasioned any annoyance. He was readmitted on the 9th of February, 1852, ulceration having attacked the integuments and exposed the bone.

On examination it was found that the osseous matter, which was liberally exuded from the broken tibia, readily united with the end of the displaced piece of the fibula which had been permanently retained, and nourished chiefly by this ingrafting. The prominent part of the spicula was not in the least degree rounded off, but remained sharp, as the moment after the accident. I cut down upon it by an incision an inch and a half long; freed the surrounding parts adherent to it, and then, with a narrow-bladed forceps, cut off the bone at the line of its attachment to the tibia. In effecting this object the anterior tibial artery had to be divided—the incision was enlarged up and down, and the vessel ligatured above and below. The wound was allowed to heal by granulation, with the object of implanting a new part, so as to guard against straining of the integuments above the joint, a position subjected to so much motion. After this operation the patient made a rapid recovery, and has been dismissed from the hospital, able to walk perfectly well.

In those cases where the spicula becomes attached by one end to the uniting callus of the fractured bones, as in the instance just recorded, the sharp extremity will not be rounded off, and it may lie under the integuments for years without producing ulceration, if no undue pressure be exerted over it from without. The following case affords a good illustration.

A man named Patrick Walsh, aged 66, was admitted into Mercer's Hospital, December 20, 1850. Having been thrown down by a car in the street, he was slightly contused over the chest and limbs; but he directed my attention to an old fracture. His right leg was broken thirty-five years before, when engaged in the amusement of kicking football; the site and outline of the fracture was nearly as evident as if it had

been a recent injury; the leg was an inch shorter than the sound one; the tibia was split from about its centre down into the lower third, the line of fracture being very oblique and traversing from without inwards, and the fibula was broken two and a half inches from the extremity of the malleolus. The tibia was arched in front, and the lower fragment of the fibula directed forwards and inwards, its upper fragment also was inclined forwards, and considerably overlapped the lower; the edge of it was quite sharp beneath the skin, threatening every moment to protrude, yet by the patient carefully guarding this part from pressure, it had continued there with impunity for so long a time.

When small spiculæ are completely isolated, they may act as foreign bodies and be cast out, but more frequently they are capable of contributing to the repair of the fracture, or, as sometimes occurs, they are surrounded each by a lymph cyst, which in many instances proves the medium of their removal by absorption.

There is one more point of interest in case No. 4, in reference to the fact that the gap, at least an inch and a half in extent between the upper and lower fragments of the fibula, and created by the large piece of its shaft "thrust in front and above the joint," was afterwards repaired and filled up by a firm osseous piece. Now, this is an important practical point, if a portion of the shaft of a bone be removed, by judicious management, a perfect osseous substitute may be procured. This fact is at variance with the doctrine inculcated by Sir A. Cooper, who maintained, that for the union of fractures it was essential that the broken bones should be kept in contact. "The first reason which I should state," says Sir A. Cooper, "for the want of union in fractures of the neck of the thigh-bone is the want of proper apposition of the bones; for if the broken extremities be in any part of the body kept asunder, ossification is prevented." Again, in support of the axiom which I have laid down, I beg to refer to some cases recorded in the twelfth volume of the *Medico-Chirurgical Transactions*, p. 167, one of which clearly proves the possibility of bony union after the removal of three inches of the tibia and the consequent separation of the bones to two inches. In Mr. Heaviside's Museum there were instances of extensive bony deposits between fractured surfaces that were not in apposition.

I shall conclude by a quotation from Rokitsansky. In his *Pathological Anatomy*, when speaking of the repair of injuries of bone complicated with loss of substance, he writes:—"Under favourable circumstances it is effected by the first intention, and the osseous mass, exuded from the surfaces of the wound in the bone, serves not merely to reunite the bone, but also to supply the place of the part which has been lost."

## NEURALGIC AMAUROSIS.

M. TAVIGNOT gives this name to the complete or incomplete, partial or general, paralysis of the nervous retina under the influence of neuralgia of the fifth pair of nerves.

"The mode of action exercised on the eye by the fifth pair of nerves affected with neuralgia, is (states M. Tavignot) subject to certain laws which I will endeavour to describe. I admit two species of neuralgic amaurosis, very characteristically distinct from each other. The one is attributable to a neuralgic condition of the extra-orbital branches of the trifacial nerve—this is the extra-orbital neuralgic amaurosis; the other arises from a neuralgic condition of the ciliary nerves—this is the intra-orbital neuralgic amaurosis. The extra-orbital neuralgia of the fifth pair of nerves appears to me to act on the retina, producing a paralysis of that membrane. This paralysis results from a want of equilibrium in the distribution of the nervous influence, as if the excessive waste of this fluid by the extra-orbital branches took place at the expense of the ciliary nerves, which would thus be more or less deprived of it. Both one and the other form of neuralgic amaurosis appear to have an analogous origin, although differing completely in their symptoms. The cause of neuralgic amaurosis, considered in a general manner, is an abnormal state of the blood, resulting from an irregular assimilation, or a vicious re-assimilation. Local treatment is not likely to be successful, unless combined with general treatment."—*Prov. Jour.*

These oracular announcements are, doubtless, very instructive and convincing to those who admire them; but for the life of us we cannot discover the importance of them. If M. Tavignot would have the goodness to prove something, we might then understand something about the matter.

## CASES OF FOREIGN BODIES IN THE EYEBALL.

By WHITE COOPER, Esq.,

Ophthalmic Surgeon to St. Mary's Hospital, and Senior Surgeon to the North London Eye Infirmary.

SINCE the publication of my paper on Gunshot Wounds of the Eye, in this journal of November, 1851, three cases of severe injury to that organ have fallen under my observation; and as points of interest are presented by each, it is proposed to relate them with the addition of a few remarks.

**CASE I. *Fragment of Flint embedded in the Eye.—Extraction.***—Thomas Trigg, a tall, spare, feeble man, aged 65, residing at Merrow, near Guildford, was received into the North London Eye Infirmary, under my care, on November 22, 1851.

Six days previously, whilst breaking stones on the road, a chip of flint flew up and struck him with great force on the right eye, cutting through the cornea, and burying itself behind the iris, between it and the crystalline lens. Active treatment was adopted; but his condition, when seen by me, was as follows.

There was acute inflammation of the conjunctiva, sclerotic, and iris; a vesicle projecting from the lower third of the cornea, near the mesial line, marked the seat of the wound through which the fragment had passed. The iris projected forwards, and was adherent at this point posteriorly, but it was also bulged by a yellowish body, a portion of which was visible through the pupil, though that was contracted and somewhat distorted. There was hypopyon; and though the lens was opaque and sight utterly extinguished, the intolerance of light was distressing. The patient complained of unceasing agonizing pain in the eye, which gave him no rest night or day.

The old man appeared quite worn down by suffering, and was by no means in a condition to bear active treatment. The pulse was slow and irregular, the skin cold and pallid, and the nervous system in a state of extreme depression. He was also under the influence of mercury, which appeared to have been very properly administered. He had travelled to town by rail, in a third class carriage, and had afterwards walked a considerable distance, which had materially aggravated his previous sufferings; the vibration of a railroad being peculiarly calculated to cause a foreign body pressing against the iris to excite irritation. He was immediately put to bed, warm tea administered, and the eye freely fomented. When reaction had been excited, four leeches were applied to the right temple, and an opiate administered. By these and similar means, including perfect quiet in a darkened ward, the acute inflammation rapidly subsided, although the neuralgic pain continued; and on the 25th I deemed the eye sufficiently recovered to render justifiable an attempt at removal of the foreign body.

The exquisite sensitiveness of the eye, and the intolerance of light, rendered chloroform indispensable; and Dr. Snow, having first ascertained that there was nothing in the condition of the heart to preclude its use, kindly undertook its administration. The patient was placed in the recumbent posture, and when fully unconscious, an incision was made with Jäger's knife through the upper and outer margin of the cornea, about the sixth of an inch in extent. A pair of Charrière's delicate curved iris forceps were then cautiously passed through the wound into the pupil, and after one or two failures, arising from the depth of the substance and the limited space in which to work, the object sought was attained, and the chip, enveloped in yellow lymph, was withdrawn. The eye, having been carefully cleansed, the corneal wound was adjusted, the lids closed, and retained with a strip of plaster, and cold water dressings were applied to the eye. The patient remained about half an hour on the couch, and when he had quite recovered from the effects of the chloroform, was replaced in bed, where he immediately fell asleep, and slept tranquilly for some hours. 26th. The patient stated that he was "wonderfully easy," more so than he had been since

the accident; the lids were quite free from redness or oedema, and there was no undue lachrymation. 29th. Nothing could have been more satisfactory than the progress of the patient so far. He had continued easy, had slept comfortably, and the eyelids bore a perfectly natural appearance. 30th. The eye was opened this day; there was no inflammation; the cornea was bright, and the wound well united. He had some perception of light, though the traumatic cataract prevented all vision.

He was discharged on the 4th of December, the eye having recovered from the operation, and being free from pain. Subsequently to his arrival at home he had some return of pain, I believe, and perhaps inflammation, but the accounts forwarded were not sufficiently explicit to enable me to form a correct opinion.

**CASE II. *Chip of Steel embedded in the Eye.***—Robert Chicken, aged 35, an athletic man, working as an engine-fitter at the Great Western Railway, became a patient of mine at St. Mary's Hospital, December 9, 1851.

On the previous day, whilst cutting hardened iron with a chisel, a chip struck his left eye, blinding him instantly, and causing severe pain. He forthwith applied at St. Mary's Hospital, and Mr. Bullock, the house-surgeon, on examination, saw that the lens had in that short interval of time become opaque. Rightly judging that the injury was severe, he ordered four leeches to the neighbourhood of the eye, belladonna to the brow, and calomel with opium every three hours. At half-past one o'clock on the 10th (twenty-six hours after the accident), the eye presented the following appearances.

Careful examination detected a clean incised wound in the cornea; and corresponding thereto was a gap in the iris, midway between the margin of the pupil on the inner side and the ciliary attachment. This wound was peculiar: a flap of the membrane, about one-twelfth of an inch in length, had been cut up, and, being attached by its outer border, swung to and fro like a miniature shutter. The wound in the cornea appeared to have closed instantly after the receipt of the injury, for the anterior chamber was full, and the iris retained its proper position; the lens was opaque, and there was barely perception of light. There was much congestion of the conjunctiva and sclerotic; the patient complained of intense pain, and there was hypopyon.

Encouraged by the result of the preceding case, and thinking it probable that the chip had lodged behind the iris in the posterior chamber, I decided to make an attempt to extract it.

The patient having been brought under the full influence of chloroform, an incision was made through the outer margin of the cornea; a fine steel probe was then introduced through the pupil into the posterior chamber, and I endeavoured, with the utmost gentleness, carefully avoiding all injury to the parts, to discover the foreign body. Thinking it was felt, a pair of fine iris forceps were used, but after searching as much as prudence would justify, without seizing the chip, and being uncertain as to its precise situation, I considered it proper to desist from any further attempt, especially as blood appeared in the anterior chamber. The lids were therefore closed with plaster, and the patient put to bed, with cold water dressings applied to the eye.

11th. I was to-day informed by the patient's wife, that he had led an irregular life, and had suffered from an attack of delirium tremens, from which he had only recovered so recently as the Saturday previous to the accident. There had been rather severe pain in the eye during the night, but the lids looked quiet, and free from tumefaction. He was ordered to continue the calomel and opium, and cold applications as long as agreeable. 13th. The eye had become perfectly quiet and free from pain, and, on opening it, I was surprised at finding it even less red than at the time of the operation. The wound in the cornea had healed, the effused blood had nearly disappeared, and the anterior chamber contained its usual quantity of aqueous humour. Beds being in great request, he was made an out-patient.

It was too much to hope that the lull in the inflammatory symptoms would last, but the eye continued quiet for several days. His mouth had become sore, and the quantity of mercury was therefore greatly reduced.

20th. He this day presented himself complaining of pain in the temple and brow. The eye was irritable, the mouth rather freely affected, the bowels were confined. He was ordered to take a pill of colocynth and hyoscyamus; to rub mercurial ointment with opium into the temple at night, and to bathe the eye frequently with collyrium belladonnæ cum opio. 27th. The eye was in a very congested and irritable state; the iris had undergone change of colour. Two leeches were ordered to be applied every other night to the left temple or mastoid process. The other treatment was continued; mercurial action still marked. 30th. He complained much of sore mouth, and less of the eye, where, however, the process of disorganization was clearly proceeding. He was ordered to take two grains of iodide of potassium in infusion of quassia twice daily, and to continue the leeches according to circumstances; the brow was to be rubbed with anodyne lotion. January 3rd, 1852. Still much pain in the eye and temple, extending over the side of the head; bowels confined; eye congested. Three leeches were applied to the left temple immediately; an ounce of *mistura magnesie sulphatis cum magnesia* was ordered to be taken every morning; and one grain of extract of opium at bedtime. 6th. There was great amendment; he had been nearly free from pain during the last twenty-four hours, and the eye was less congested. It was, however, soft to the touch at the upper and outer part. He was ordered to take half a grain of extract of opium every night, and to go on with the mixture in the morning.

With slight variations and occasional leechings, this treatment was continued until the 16th of February, by which time the eye had become quiet, but the process of atrophy had made manifest progress. He was now ordered *mistura quinae*, an ounce twice a day, and to continue the collyrium, which had been steadily used throughout with great advantage. He had resumed work, and stated that the eye had not suffered in consequence. His condition at present is such as might be expected. The eye has diminished about one-third in size, and is soft; the iris is discoloured; the pupil distorted, contracted, and drawn downwards and inwards; the sclerotic is of a yellowish brown hue; all vision is extinguished.

**CASE III. Penetrating Gunshot Wound of the Eye.**—On the 3rd of January, 1852, I was requested by Mr. Ancell of Norfolk Crescent, to visit one of his patients, who had received a formidable injury to the left eye a few days previously. He was standing on the brink of the Serpentine, when a gun, loaded with partridge shot, was discharged at the distance of about thirty yards from him, and a pellet, glancing from the water, struck his eye, instantly extinguishing the sight. The elevation of his head above the level of the water at the time, was about eight feet. He was of a tall, rather corpulent frame, lived well, and bore the general aspect of plethora. Acute inflammation speedily set in, and continued with severity, notwithstanding the most judicious treatment. His condition when seen by me was as follows, premising it by stating that his eyes were naturally full, and the irides gray, with a yellowish pupillary margin.

The left eye was acutely inflamed, the conjunctiva, sclerotic, and iris being all involved. Just beneath the circumference of the cornea, nearly in the mesial line, there was a ragged wound, the surface of which had a peculiar whitish appearance, as if it had been scorched. In the centre was a black spot of prolapsed pigmentum nigrum. From this point, the conjunctiva, surrounding the lower half of the cornea, was raised by chemosis. The iris was much discoloured, being of an olive green, streaked with reddish lines, and the pupil was drawn down in a linear figure to the wound. Immediately after the infliction of the injury, the anterior chamber had been filled with blood, which retained the iris in its place; but as this

became absorbed, the iris prolapsed through the wound, dragging the pupil down as described. It may be mentioned that the patient insisted that the shot could not have penetrated the eye; but on this point I believe him to have been in error.

To proceed with the description of his condition on the 3rd of January:—The pupil was absolutely immoveable, and there was not the faintest perception of light. There was severe pain in the ball of the eye and temple, with hemicrania aggravated at night. When the eye was turned briskly outwards, a sharp pang was felt, and a flash of light was excited. On the most careful examination, the crystalline lens seemed perfectly clear and sound.

The opinion at which I arrived, after mature consideration, was, that the shot had entered the eye, and passing under the lens without wounding it or opening its capsule, had lodged either in the upper and posterior part of the sclerotic, or had possibly passed through that and buried itself in the orbit; but most probably the former.

The treatment agreed on by Mr. Ancell and myself, was absolute quietude, depletion by repeated applications of leeches, mercury to the extent of affecting the mouth, opiate fomentations and belladonna to the brow. The symptoms slowly gave way; and on the 22nd of February, when the eye was again examined by me, it had undergone the following changes.

The globe was perceptibly diminished in size, and was flaccid to the touch; the sclerotic had a dingy yellowish brown hue; the iris was dull green; the pupil fixed in the condition first described, by a fringe of dark red adhesions, binding it to the capsule of the lens. The seat of the wound was indicated by a small red spot; all pain had subsided, but there were occasional flashes of light. The sight was extinguished.

**Remarks.**—A striking feature in two of the cases which have been related, was the marked relief of inflammatory action which followed the performance of the operations. *A priori*, it might have been anticipated that the additional infliction of an incised wound upon an eye already inflamed, together with the irritation inseparable from the introduction of forceps into so sensitive an organ, would have brought on acute ophthalmitis. Far from it. In the first case, the most decided relief was afforded, and the previously existing inflammation rapidly subsided. In the second, although the attempt to remove the chip of iron was unsuccessful, the wound healed kindly, the pain subsided, and for several days, until in fact secondary inflammation set in, the progress of the case was highly satisfactory; and this was more remarkable from the fact of the patient having, only two days before the occurrence of the injury, been suffering from delirium tremens, the effect of excessive drinking. How often does it happen in ophthalmic practice, that an operation for extraction of cataract, performed with the utmost skill and gentleness, and under the most favourable circumstances, is followed by destructive inflammation, whilst other eyes will bear with impunity an amount of violence scarcely credible.

Inflammatory symptoms, excited by a foreign body in the eye, are doubtless efforts on the part of Nature to expel it; or, failing that, so to enclose and embed it in lymph, as to render it harmless. There have been instances mentioned by Ammon, Salomon, Grüllerich, and Mackenzie, where foreign bodies, lying in the anterior chamber, have been in this manner encysted, and have ceased to be productive of irritation. We may fairly ascribe the absence of acute inflammation after such operations as have been described, to the circumstance that Art has achieved the object for which Nature was vainly striving, and that the relief afforded, more than counterbalanced the injury inflicted.

When a foreign body has lodged in the eye, and cannot be extracted, atrophy of the globe is a common result. The active symptoms, of which neuralgia is one of the most distressing and lingering, gradually subside. The iris remains permanently discoloured, and the fibres indistinct; the pupil, distorted and motionless, is bound to the surface

of the capsule of the lens by dark adhesions; the lens may be converted into an osseous cataract, or, if the capsule has been opened, may undergo absorption; the sclerotic, thinned in texture, permits the dark hue of the choroid to be seen imparting to it a dusky tint, whilst the surface of the soft and shrunken globe is traversed by a few large tortuous purple vessels. Such, if the eye be not in the first instance destroyed by suppuration, are the general characteristics; and the appearance of the iris is one test by which our judgment may be guided as to the presence of the foreign body in the eye, for patients often declare that it is impossible that it *can* be in the eye. Iritis, excited by a simple wound, may be expected to subside, and the iris to recover its natural colour, under the use of mercury. Not so when a foreign body has lodged in the eye. A blue or gray iris then becomes a dingy green, and a brown iris acquires a muddy reddish colour, doubtless from the interstitial deposit, to which the change of colour is due, not being removed by absorption. It has been said, that a yellowish, more or less elevated swelling of the membrane, indicates the locality of the foreign body. It may be so when it is in contact with the iris; but I have not observed it in other cases, though, when the substance is in the posterior chamber, the pupil is often drawn in an angular form towards it.

During the secondary inflammation, arising under the circumstances described, the repeated application of two or three leeches to the temple or mastoid process, is of essential service. A larger number are not desirable, the object being simply to unload the vessels without exhausting the system.

I have on several occasions been consulted as to the propriety of attempting to restore sight to an eye damaged by accident. The patient has probably perception of light, and clings to the hope that he may regain some useful vision by submitting to an operation. There are two points to be borne in mind, in reference to a question of this description—Is it possible to improve the sight? Is it desirable?

There will probably be two proceedings open for consideration—namely, the removal of the opaque lens, and the formation of an artificial pupil. If the injury has been comparatively slight, and the eye is generally healthy, though dark from traumatic cataract, sight would be restored by removing the lens from the field of vision. If there has been iritis, which has bound down the pupil to the capsule of the lens, but the globe remains firm, and the retina sound, artificial pupil, with or without destruction of the lens, may offer a fair prospect of restoring sight; but if there be atrophy of the globe, fluid vitreous humour, a discoloured and paralysed iris, there is certainly serious disorganization, and an operation would be of little avail.

Then, as to the propriety of operative interference, if the patient has one sound and strong eye, the other being blind, it becomes a serious question whether the restoration of imperfect sight to the latter may not be a positive disadvantage. An artificial pupil could scarcely be made perfectly in the centre; consequently the axes of the two eyes would not correspond, and double vision would exist. If the lens were removed, the sight of the two eyes would materially differ, and perplexing confusion be caused. In more than one instance, I have been actually requested by persons (generally artisans, who have received an injury impairing, but not extinguishing, the sight of one of their eyes) to “put the eye out,” as they expressed it, so annoying and trying was the confusion it caused. So persons who have cataract partially formed in one eye only, acquire a habit of closing that eye when reading, as it interferes with the other. It is our duty, therefore, before undertaking an operation, to satisfy ourselves that we shall leave the vision of the patient better, and not worse, than we found it. But when from any cause the sight of the uninjured eye has become imperfect, and threatens to depart, then a great boon may be conferred upon the individual by calling into use, by well-applied skill, an eye which had been previously useless.

Chloroform is of essential service in facilitating operations on inflamed eyes. Without its aid, indeed, they could not be satisfactorily performed; for when the eye is in this condition, its sensibility to light and to touch is so increased, and the spasmodic action of the orbicularis palpebrarum and muscles of the globe is so violent, that force is required to keep the lids open, and the eye must be held steady by instruments—proceedings highly objectionable. All this is obviated by the use of chloroform; and by attention to two points it may be used with perfect confidence. First, it should be administered on an empty stomach, as vomiting then very seldom arises. Secondly, soon as the operation is concluded, the lids should be secured by a strip of adhesive plaster, extending from the brow to the cheek. This prevents any disturbance of the wound during the return to consciousness; and, by supporting the lids and eye, if vomiting should occur, prevents expulsion of the contents of the globe. Siehel's canula-forceps are most useful in extracting foreign bodies from the interior of the eye; indeed, if the body is not too large for their grasp, I should never use any other description. For the preliminary corneal incision, Jäger's double edged spear-pointed knife is the best instrument with which I am acquainted.

There is an affection which the patients whose cases have been related have hitherto escaped (I can speak as to three of them, at least), which is occasionally a sequence of foreign bodies in the eyeball. I allude to that formidable inflammation of the uninjured eye, called by Dr. Mackenzie “Ophthalmia Sympathetica,” on which some valuable remarks are contained at page 302 of Dr. Jacob's “Treatise on the Inflammations of the Eyeball.” It is an inflammation which involves the various tissues of the eye, coming on five or six weeks after the infliction of the injury on the other eye, just when the patient is congratulating himself on having escaped from the trammels of an irksome confinement. It occurs most frequently in feeble cachectic habits, and in constitutions prematurely worn out by dissipation; and for this reason it is, unfortunately, very little amenable to treatment. To improve the general health, and give vigour to the system, is the chief indication; but a guarded prognosis should always be pronounced, as it is a tedious and intractable disease.—*London Journal of Medicine.*

We have given Mr. Cooper's paper in full, although our readers have already had an opportunity of acquiring information on the same subject from a communication by Dr. Jacob, published in the *MEDICAL PRESS* of December 9, 1846, which Mr. Cooper has evidently never seen. The subject is one worthy of the attention of surgeons, for there are many erroneous views entertained respecting it.

### A HAIRY WOMAN.

Described by Dr. CHOWNE of Charing-Cross Hospital.

A PERSON came to this hospital, requesting to have a testimonial as to the sex of the individual, who is the subject of these observations. The request was accompanied by a statement that she was under an engagement to marry, but that the masculine appearance of her face produced scruples in the mind of persons who would otherwise have performed the marriage ceremony. Her name is J. B—; she is aged 20, a native of E—, in Switzerland, and by occupation a needlewoman. She states that at her birth she had, as she has been informed by her parents, a beard: that is to say, a considerable quantity of hair growing on those parts of the face usually occupied by the beard and the whiskers in men, except on the upper lip and on the hollow immediately under the lower lip. It was at her birth, she states, about as long and as thickly spread as it usually is on a man's arm; in other respects she was not different from other female children. The beard grew gradually, and when she had attained the eighth year of her age it was two inches long. At about eighteen years of age catamenial functions commenced, and have continued

perfectly normal. She has had, and still has, very good health. Her occupations and dispositions are all womanly.

At the present time, the beard and whiskers are what would be called very abundant, full, and strong, exceeding in quantity even that of the beard and whiskers of men generally in this country. It grows also on the parts covering the cheek-bones, under the eyes. Those parts of her face which were without beard at her birth, are still without. The hair forming the whiskers varies in length from one to four inches; that of the beard is about the same length. It is all strong, and rather coarse, as well as being very thickly set. She states that it does not require cutting. When she appears in public, she has a handkerchief folded three-cornerwise on her head, put on so that two of the corners pass down over the sides of her face, and meet just below the mouth, thus concealing the peculiarity. As the handkerchief cannot be worn so as to conceal that part of the face over the cheek-bone (as it would then cover the eyes also), she shaves that part. In her own village, where she was well known, she had no occasion for the handkerchief, but in a strange place she finds it necessary, lest the police should regard her as a man disguised in woman's apparel.

The hair growing from the crown and back part of the head is two feet and a half long, and that growing from the front part of the head two feet. Both the front and back hair is moderately abundant, not excessively so. It is neither fine nor coarse; the colour dark brown; that of the whiskers and beard the same.

On the neck and on the parts just below the clavicles, are numerous hairs thinly spread; much coarser and longer than the hair generally visible there in men. On the shoulders, arms, and forearms, to the wrists, there is a quantity of hair, about equal to what would be found in a man moderately hirsute, but more uniformly spread over the whole circumference of these limbs. The mammae and the whole of the sternal portion of the chest are quite free from hair, indeed quite fair. The breasts large, fair, and strictly feminine in all respects, including papillae and their areolae. On the back part of the shoulders there is also a good deal, and a tolerably broad line of dark hair extends down the back, sufficiently abundant to give quite a dark appearance in the line or depression over the vertebral column. The nates and the parts covering the tuberosities of the ischia, all have hair pretty uniformly spread, and in quantity about as much as would be on the limbs of a more than commonly hairy man. The anterior surface of the abdomen, extending from the umbilicus to the pubal and inguinal regions, has the masculine quantity and the masculine distribution. The surfaces of the inferior extremities, to the ankles, are in the same state, excepting only the knees and hams, which are in the more ordinary state.

She is of short stature. The form of the head is not remarkable. The upper part of her thorax and the pelvis are feminine; her legs and knees less so. The feet small. The arms and the hands small and feminine. She has not any malformation of any kind. Dressed as a man she would not have anything *particular* to betray her. Her manner, however, appears to be gentle, and would constitute a contrast to man's attire. Her voice, in conversation, is not remarkable either way. She sings occasionally, and then it is feminine.

She states that in her own country it was deemed that there must be within the abdomen, organs male in their character, both corresponding to the superfluous hirsute growth, and accounting for it. She was, at the time of my seeing her, about five months advanced in pregnancy. Besides the usual and less certain signs, the foetal cardiac sounds were audible.

Her mother's complexion was neither dark nor fair, but between the two. Her father was of dark (brown) complexion, and had not much beard or whiskers. Her mother's father was remarkable for having both whiskers and beard extremely large. She has one brother, man grown, who is, she states, almost entirely beardless; and two sisters not different from other young women. Her mother does

not attribute the peculiarities to fright or other cause that she has any knowledge of.

In almost all instances where the general contour or aspect, or other secondary peculiarities, indicative of the sexes, are blended in the same individual, obvious specific malformation, or excess, or deficiency, or a combination of the primary peculiarities of sex, has been found.

In this case, however, there is a series almost complete of masculine indications or peculiarities of the general or secondary character, apparently in the *entire* absence of specific malformation, or excess, or deficiency, or combination, presenting an example to be classed amongst accidental growths of hair, rather than amongst such special growths as are the consequences of special physiological influences.

With reference to the possible existence of a concealed organ or organs in the subject of these remarks, it is worthy of notice, that, although the superfluous growth is in some respects favourable to the supposition that such organs do exist, in other respects it does not favour that view. The beard, for example, existed *at birth*, and at *eight years old was two inches long*—thus anticipating the period of puberty instead of accompanying or following it, and proceeding altogether in advance, and *apparently independently*, of special organic influence. The beard was, and still is, confined to certain parts of the face, and is absent on others, where, in accordance with special influence, in a male, it should have been present, as on the upper lip and under the lower. On the whole of the anterior part of the trunk above the umbilicus, where, in accordance with the same influence, it should be even especially abundant, it is wholly or very nearly wholly absent. These circumstances conspire to weaken the supposition that there are concealed male structures, and to strengthen the probability that the superfluity of hair belongs to the accidental class.

*Accidental Growths of Hair.*—Accidental growths of hair are nearly, if not entirely, confined to the skin, the mucous membranes, and the interior of cysts. The physiology of the latter too is not without its extreme, if not insuperable, difficulties, and indeed many of the productions found in these situations having been ascertained not to be hair, but only resemblances to it, has involved the subject in extreme uncertainty, as well as difficulty. Those cases in which hair is said to have grown on the tongue, the pharynx, and the interior of the intestinal canal, where no hair follicles exist, may also be regarded as instances difficult, if not impossible, of solution.

As in the present instance there is not anything to indicate that the hirsute peculiarity has for its origin concealed masculine structure, except the situations which it occupies, it may be regarded as analogous to other examples of similar growth, which appear to be purely accidental. We may therefore regard it as very doubtful whether special primary organic structure is necessary to the production of hirsute growths, even of masculine character.

Several cases considered to be accidental have been attributed to frights prior to the birth of the child—modes of accounting for them which have been participated in by the mother. Other examples of hirsute growths not congenital, have been attributed to disease affecting the system generally; others to local disease.

I had occasion to see, some years since, a child which had at birth a patch of hair on the shoulder, which when the child was about four years of age was nearly as large as the palm of a small hand; the hair was fawn colour, and in thickness and length closely resembled the hair of that animal; indeed, the patch looked very much like a piece of fawn-skin in its natural state. This was attributed by the mother to her having been startled by a fawn which unexpectedly skipped by her. She states that at the moment she involuntarily raised her hand, and touched the part of her shoulder corresponding to that on which the patch of hair described grew.

A case was published at Venice, in 1815, and was much discussed in the German journals soon after. In the course

of legal proceedings it transpired, that "a lady, aged 27, much admired for her beauty, had, on her person, from the breast to the knees, a profusion of black, thick, and bristly hair."

A case is recorded by Mr. South, of a male child, who at the time of his birth was completely covered with hair, and the back of his head particularly with black hair, about the length usual to children of four or five months.

A very remarkable case is recorded in which a female had not only hair all over her body, but also a very profuse and thick beard, and indeed on every part of her face; the description states that it *was* so, and is accompanied by an engraving representing it as being so. It is to be inferred, however, that the limbs were not in the same state, as the hands and forearms are represented as being free. "In the year 1655 was publicly shown, for money, a woman named Augustina-Barbara, the daughter of Balthazar Ursler, then in her twenty-second year. Her whole body, and even her face, was covered with curled hair, of a yellow colour, and very soft, like wool; she had, besides, a thick beard that reached to her girdle, and from her ears hung long tufts of yellowish hair. She had been married above a year, but then had no issue. Her husband's name was Vaubeck; he is said to have married her merely to make a show of her, for which purpose he travelled into various countries, and among others visited England." This account of her is published amongst the Portraits, Memoirs, and Characters of Remarkable Persons, from the reign of Edward the Third to the Revolution, by Mr. J. Caulfield. He proceeds to say: "If I conjecture right, she is that very hairy girl mentioned by Bartoline, and appears to me not to differ from her whom Borelli describes by the name of Barba; who, he believed, improved, if not procured that hairiness by art. But whether she is the same that the famous Vitruvius saw at Rome and Milan I dare not affirm, for he hath nowhere mentioned this country-woman of his that I know of."—*Lancet*.

#### ON THE USE OF KOUSSO.

UPON looking over some works upon Ethiopia and Abyssinia, I find the following accounts of the koussou, and have extracted them under the impression that they may be of interest to some of your readers. The first is taken from a New History of Ethiopia. By the learned Job Ludolphus, Counsellor to his Imperial Majesty of Saxony, &c. The date of this, the second edition of the English translation, is 1684. There is another tree which Godignus praises, most excellent against the worms in the belly: a distemper frequent among the Abessines, by reason of their feeding upon raw flesh. For remedy whereof the Habessines purge themselves once a month with the fruit of this tree, which causes them to void all their worms. In the appendix upon natural history, published in 1790, with the large edition of Bruce's Travels, there is a minute account of the tree which he calls *Cusso* or *Banhesia Abyssinica*. The *cusso* is one of the most beautiful trees as also one of the most useful. It is an inhabitant of the high country of Abyssinia, and indigenous there; I never saw it in the Kolla, nor in Arabia, nor in any other part of Asia or Africa. It is an instance of the wisdom of Providence, that this tree does not extend beyond the limits of the disease of which it was intended to be the medicine or cure. The Abyssinians of both sexes, and at all ages, are troubled with a terrible disease, which custom, however, has enabled them to bear with a kind of indifference. Every individual, once a month, evacuates a large quantity of worms; these are not the tape-worm or those that trouble children, but they are the sort of worm called ascarides, and the method of promoting these evacuations is by infusing a handful of dry *cusso* flowers in about two English quarts of *bouza*, or the beer they make from *teff*; after it has been steeped all night, the next morning it is fit for use. During the time the patient is taking the *cusso* he makes a point of being invisible to all his friends. . . . The *cusso* is planted always near churches, among the cedars which surround them, for the use of the town or village.

The whole cluster of flowers has very much the shape of a cluster of grapes, and the stalks upon which it is supported very much like the stalk of the grape. The flower itself is of a greenish colour, tinged with purple; when fully blown, it is altogether of a deep red or purple. Bruce gives two plates of the tree, and thinks it probable that it may be found in 11 deg. or 12 deg. north latitude in the West Indies or America. He also says:—"It is alleged that the want of this drug is the reason why the Abyssinians do not travel; or if they do, most of them are short lived." The fact that both these writers allude to the monthly discharge of worms is very curious, and of course founded upon the truth, as they record it independently of each other, at an interval of more than a century, upon their own personal observation; and it is scarcely necessary to add, that if the plant was a cure for worms, there would be no occasion to take it so frequently; and, moreover, if the supply was as plentiful as described, the disease might have been destroyed, supposing it to have been curable by the koussou. Recent hospital records, founded upon long experience in this country, have proved that it is a useful remedy, but not more to be relied on as a means of radical cure than many others we have nearer at hand.—*Mr. Augustin Prichard in Provincial Medical and Surgical Journal*.

#### REVIEWS AND NOTICES OF BOOKS.

THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA. By JOHN HARRISON, F.R.C.S.E., and formerly Lecturer on Surgical Anatomy. London. 1852. 8vo. pp. 104.

DISEASES of the urethra (the author observes), in a modest and unassuming preface, have occupied his attention for many years, and he has been induced to publish this treatise in the hope that "the principles laid down, and the modes of proceeding inculcated, may, at all events, assist the younger members of the profession in surmounting the many difficulties they may encounter in the treatment of stricture of the urethra."

The author commences by giving an outline of the anatomy of the parts concerned in stricture. In this place he quotes Mr. Quekett's description of the mucous membrane of the urethra. Mr. Quekett divides the urethra into three parts, the prostatic, the membranous, and the spongy portion.

"In the first or prostatic portion, the mucous membrane at its commencement is smooth, and it then becomes thrown into longitudinal folds, which pass in curved lines on either side of the verumontanum; in this portion of the canal we have the openings of the prostatic ducts.

In the membranous portion, the mucous membrane is again smooth, and very vascular; but immediately on passing the bulb, it diminishes in vascularity, and becomes of a bluish tinge, resulting from strongly glistening fibres like those of tendon, which are here present. The canal is thrown into longitudinal rugæ, which are continued on to within three inches of the glans; from this part, the membrane is more or less villous during the remainder of its course.

The mucous membrane of the entire canal is covered with that variety of epithelium termed the tessellated or scaly; in the spongy part it is in tolerable abundance, but in the membranous it is more sparingly developed; in the prostatic, and near the cervix of the bladder, the scales become more rounded, and somewhat resemble those of the kind termed spheroidal. There is in most urethræ a distinct line of demarcation between the membranous and spongy portions; the vessels of the former being very numerous, and almost superficial; whilst in the latter, they are intimately connected with the fibrous tissue above noticed. The vessels in the grooves of the rugæ of the spongy portion are far more numerous than those on the convex parts, forming the folds themselves."

Some writers attach a good deal of importance to measurements of the different parts of the urethra; but if we take into account (the author observes) "the many circumstances which tend to modify both its length and calibre, and the fact that these vary in different individuals, and undergo material changes as age creeps on, we must conclude

that no specific or definite admeasurements can be assigned which shall be worthy of reliance."

Mr. Harrison next gives a concise description of the arrangement of the veins of the penis. "The vena magna ipsius penis is seen (he observes) lying on the dorsum penis, and just before it passes under the pubic arch, divides into numerous capacious tortuous branches. These veins are in contact with the upper part and sides of the membranous portion of the urethra; they pass into the pelvis, and form the prostatic plexus. These veins pass through apertures in Wilson's muscles, and must be more or less influenced by the contraction of its fibres."

"All the blood from the glans penis, the corpus spongiosum, and the bulb, is returned by this vein and its branches. On the other hand, the blood from the corpora cavernosa is returned by branches which accompany the arteries of the corpora cavernosa, and which discharge their contents into the internal pudic vein. Therefore, as far as regards the veins, the corpus cavernosum is nowise influenced by the compressor muscle of the urethra."

We thus see that the venous blood from the urethral portion of the penis is conveyed by one channel, and that from the cavernous by another. Were it otherwise, or rather were it not for the outlet by the internal pudic vein, there would be constant risk from over-distension, or even rupture of the walls. This would therefore appear to be a salutary provision of Nature against any stress upon the vessels from undue muscular contraction."

The practical part of the treatise commences with a description of "spasmodic stricture," and "organic or permanent stricture," followed by an account of the secondary pathological effects of the latter, and of the method of ascertaining the seat and nature of the obstruction. The following is Professor Bigelow's mode of taking an impression of a stricture, as quoted by the author. He takes a medium sized bougie, made of gutta percha, the end of which is "passed rapidly to and fro in the edge of the flame of a candle until it is so warm as to be indented by the nail, the mass will remain plastic after the surface has ceased to be hot, and may be quickly carried down to the stricture, being very smooth and pliable." "If it be pressed against the obstacle for a minute with a force equivalent to the weight of one or two ounces, and then left within the part triple this space of time to cool, it will present, when slowly and carefully disengaged from the stricture, a firm, unyielding, and most accurate impression." "The gutta percha used for this purpose should be perfectly pure, and no warm water should be employed in preparing it, as the steam given off by it has a tendency to soften the bougie for several inches, and render it liable to curl up against the stricture, like a small elastic bougie."

The treatment of stricture is considered under the heads, "treatment by dilatation," "treatment by caustic," "treatment of retention," "forced catheterism," including "puncture of the bladder, puncture through the perineum, puncture by the rectum, puncture above the pubes," "comparative merits of these operations," and "incision of the stricture." Under one of these heads, Mr. Syme's operation is described. "I may here briefly advert (the author observes) to an operation devised by Mr. Syme for the cure of the gristly or resilient stricture, which, although still permeable by a bougie, resists all ordinary attempts at dilatation." "The results of this operation in London are unsatisfactory. Some of the patients who have undergone it, succumbed from the shock to the system; others from hæmorrhage, and a few of the remainder are now incommoded with perineal fistula. It would seem, indeed, that the cases in which it is at all admissible are of exceeding rarity."

The remainder of the volume is occupied with a brief account of "disease of the prostate, abscess in the perineum, catarrh of the bladder, affections of the testicle, and morbid irritability of the urethra." In an appendix the author has

given four engravings illustrating some of the chief points alluded to in the preceding pages.

We think that Mr. Harrison has well fulfilled his self-imposed task. His descriptions of disease are concise, but clear; and his practical remarks prove that he has had a fair share of experience in the treatment of the affections which he has undertaken to describe.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MAY 12, 1852.

### DEFECTS OF MEDICAL GOVERNMENT.

WE are not aware that any other class in the community complains so bitterly as the medical of the sinister influence of imperfect organization upon their destinies. In other pursuits and professions there seems to be some remedy for the correction of evils, some power by means of which harmony, more or less, is secured in the operations of component parties; but in our body it seems as if no arrangement can be devised adequate for such a purpose. In vain have Universities, Colleges, and Boards been established for the enactment of laws and the execution of them; in vain have Charters been granted by the Crown and Statutes passed by Parliament to preserve order and secure uniformity; for the very method adopted to effect the object appears to be the cause of its defeat: the remedy, in fact, seems to be worse than the disease. In our last number we exemplified this by an enumeration of the various institutions which at present vie with each other in endeavours to evade laws and relax discipline in relation to education, and we might now do the same by a demonstration of the effects of individual exertion to obstruct the exercise of any authority, and to destroy all unity of purpose. No sooner do some members of our body discover that the operation of any law or regulation is inconvenient or injurious to their interests, than they straightway call for its repeal or alteration; never once considering that it may be very convenient and useful to others. There seems to prevail, in fact, a most unreasonable impatience of restraint whenever that restraint interferes with the freedom of action necessary for the attainment of a favourite object; and a most lamentable disinclination to adjust personal interests to existing arrangements. The vociferous exclamations we often hear against laws and their operation often reminds us of the sea-sick woman who cries out to stop the ship; and the bitter reproaches poured out upon all who execute these laws, as often warn us to avoid such duty. Unfortunately, too, these clamorous complaints do not prove a *brutum fulmen*; for so weak is the authority of medical law, and so unsettled the interpretation of it, that any man can drive his coach-and-six through it. So little, indeed, is the confidence in its powers, that we every day find men, in utter ignorance of its provisions, substituting their own crude conceptions in lieu of it; yet after all, this indulgence in an apparent freedom from control and rejection of authority fails to satisfy, and those who avail themselves of it are found in the sequel complaining that they know not what to do, so contradictory are the results: they know not which way to turn them, for universal suffrage, vote by ballot, and annual parliaments, serve their purposes no better than the despotism of a self-elected close corporation, secret in its deliberations and irresponsible for

its acts. For this state of things many remedies have been proposed, and some of them have been submitted to the test of experiment. Of these, the representative system has been for some time the favourite one; and with reason, seeing its application in the formation of one branch of the legislature, of municipal corporations, and the local executive of the poor-law. Yet, hitherto, it has been but sparingly adopted; indeed we may say only in one instance, the College of Surgeons of Ireland; for the partial and cautious application of it to the College of Surgeons of England has not yet had time for its full operation. Even in the former body it is still restricted, the elective franchise being conceded to Fellows only, leaving the Licentiates unrepresented, on the ground that additional qualification is required to entitle a party to exercise the right. Be this right or wrong, politic or impolitic, it matters not much at present, because there is a constituency of Fellows quite large enough to test the value of this method. There are some five hundred Fellows entitled to vote for the election of President and Council, and that is sufficient to try the question, even admitting that not one half of them can exercise their influence, personal attendance at the election being required. But it is not in the application of the representative principle alone that the College of Surgeons of Ireland differs in its organization from the other medical institutions; it is also distinguished by a provision enabling its Fellows to hold meetings to deliberate upon its affairs, and to express opinions as to the measures adopted or contemplated by the Council: a privilege which, although conferring neither legislative nor executive powers, enables them to exercise an important influence. Notwithstanding, however, this comparatively popular constitution, we find its value so little understood that many are as loud in their complaints of its operation as they are of the arbitrary proceedings of the most exclusive medical corporations, never once recollecting that if it does not work effectually it is more or less owing to their own neglect of duty, or vicious exercise of their electoral functions. Such men forgetting their own responsibility in the matter, or even contributing by their votes and expression of opinion to the perpetuation of abuses, are loud in their condemnation of others, while they themselves are really the parties to be blamed. The elector, it seems, is at liberty to bestow his vote or express his opinions as suits his fancy, his interest, or his inclination, and the elected are to be answerable for the consequences. This may, perhaps, be the natural result of the arrangement to which we allude, but it is not a happy result, for it leads to conflicting views, and thereby to want of harmony in the conduct of affairs. In such a body the Member or Fellow is not a mere voter, like one of a parliamentary constituency, he has duties to discharge not less important in their way than those assigned to the Councillor; and our object in these observations is to remind him of his obligations, for on his due discharge of them the welfare of the medical profession may often depend. Instead therefore of deciding upon important matters without taking the trouble to ascertain the true nature of the questions at issue, or of acting upon *ex parte* statements obviously partial, he is bound to make himself master of the subject upon which he undertakes to judge. We know not anything more provoking than the common practice of hastily rejecting suggestions entitled to consideration in relation to medical affairs, without pausing for a moment to inquire as to their value; or what is worse, rejecting them because

they emanate from one individual and not from another. Not much less to be condemned is the practice of pronouncing in a summary and impatient way upon measures, in utter ignorance of the legal difficulties which surround them, and which it is hard enough to surmount without having to encounter unreasonable or intemperate opposition. Above all things, the ready credence given to the incredible stories and manifest perversions by the inexperienced is to be regretted, for it leads to such angry rejoinders and such hostility of feeling that the transaction of business becomes seriously impeded. Credulity and misrepresentation, in fact, cause more inconvenience than is generally supposed. At this time of the year when elections are impending, the scandals known as "electioneering lies" may be laughed at by some, but at other times the practice of such tactics is most reprehensible. We find, however, that in pursuing this subject we are entering into details which might as well be suppressed: examples and illustrations are, however, necessary to complete a discourse on principles.

#### MEDICAL AID IN LUNATIC ASYLUMS.

WE lately had to congratulate our readers on the successful result of the exertions of the Inspectors of Lunatic Asylums in Ireland to secure adequate remuneration for Officers of Lunatic Asylums. It seems from the following that they have not been so fortunate elsewhere:—

An advertisement has lately appeared in the public journals announcing the intention of the Middlesex magistrates to elect a medical officer for the female department of the Colney Hatch Lunatic Asylum. Without attributing the retirement of one of the medical officers to any other than private grounds, and without wishing to throw discredit upon the general management of the asylum, which is, in nearly all respects, worthy of the highest admiration, we take the present opportunity, between the secession of one physician and the appointment of another, to protest most strongly, on the part of the public, of the profession, and of the unfortunate inmates of this and similar institutions, against the niggardly system which prevails in the appointment and the remuneration of the medical superintendents. The asylum at Colney Hatch is, we believe, the largest institution of the kind in Europe; the area which it covers is most extensive; and no less than 1200 lunatic patients are now confined within its walls. Of these about 450 are on the male side, and about 750 on the female side. It is for this latter department that the services of a fully qualified medical practitioner are now required. The candidate is to be a Doctor of Medicine, a Fellow or Member of the Royal College of Surgeons, and a Licentiate of the Apothecaries' Company. The duties, although not all specified in the advertisements, may readily be described. The physicians reside constantly in the asylum; they abandon all other practice and pursuits; they keep records of all the cases, and the post-mortem examinations; they classify and arrange the cases; they superintend the general management of all the patients, and they attend upon them day and night; they furnish information to the medical and other authorities who may visit the asylum to inspect the patients and report upon their condition. In the name of justice, in the name of common sense, can it be supposed that the care and management of 750 lunatics can be undertaken by one medical man without the sacrifice of his own bodily and mental health, if he conscientiously endeavour to perform his duties; or can it be expected that any medical man of standing or reputation in his profession, will thus offer himself up as a living victim to the county for the paltry sum of £200 a year. We shall probably be met by the assertion that there are plenty of medical men to be found who would be willing and anxious to accept the office, even upon lower terms than those which are offered; but this paltry argument deserves nothing but contempt, as it is a well known fact that the cheapest article is generally the worst, and that adequate professional talent deserves, and ought to receive, an equitable remuneration. Those who entertain opposite opinions may, perhaps, derive some gratification from witnessing the degradation of an honourable profession; but it is our duty, as journalists anxious to uphold the dignity of our order, to

protest loudly against such principles being reduced to practice at the expense of our common respectability. The appointment of only two medical men to so large an establishment as that at Colney Hatch is a preposterous piece of absurdity. The number ought, at the very least, to be doubled. By having an adequate medical staff, the asylum at Colney Hatch, with its vast multitude of patients, might become one of the most useful institutions of its kind in the world, not only by affording a refuge for the victims of mental aberration, but also by supplying abundant and available opportunities for the study of diseases of the brain.—*Lancet*.

#### CORRESPONDENCE.

##### DISPENSARY BUILDINGS.

THE following brief correspondence settles a point of some importance, which might otherwise be considered doubtful. In many cases the establishment of the Dispensary on the spot where the Surgeon resides may prove very convenient, although in some it might be otherwise:—

*To the Poor-law Commissioners.*

GENTLEMEN,—There is some difference of opinion relative to the interpretation of the 11th clause of the Medical Charities Act, as to whether the medical officer, being a paid officer, or any member of committee of management, can give at a rent a house in which the dispensary is to be held, without incurring the penalty of £50, when he does not supply any medicines, instruments, furniture, or goods, or any other article for the use of the dispensary. I shall feel greatly obliged if you be good enough to inform me on the point at your earliest convenience. The Killaan Dispensary had been always held in a house of mine, and the committee of management at its first meeting, on the 16th instant, considered that the act did not apply to the dispensary house, but to the goods, medicines, &c. &c. &c., to be supplied for its use, consequently nominated the same house the dispensary house, at a rent which I would receive if legal.—I remain, gentlemen, your obedient servant,  
JOSEPH PRATT, the Medical Officer.

Killaan Dispensary District, in the Ballinasloe Union,  
Kilconnell, April 28, 1852.

*Reply.*

Poor-law Commission Office, Dublin, May 1, 1852.

SIR,—I am directed by the Commissioners for administering the Laws for the Relief of the Poor in Ireland, to acknowledge the receipt of your communication of the 28th ultimo, in which you request the Commissioners' instructions relative to the interpretation of the 11th clause of the Medical Charities Act, as to whether you, as medical officer of the Killaan Dispensary District, can let your house at a rent for the use of the dispensary without incurring a penalty, and in reply I am to state, that there is not, in the opinion of the Commissioners, anything in the 11th section of the Medical Charities Act to prevent you from letting an unfurnished house to the committee of management of the Killaan Dispensary District, to be used as a dispensary house.

By order of the Commissioners,

To Dr. J. Pratt, &c.

E. STANLEY, Secretary.

##### INSURANCE COMPANIES.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—As attention has been directed lately, through the medium of your widely read journal, to the subject of Insurance Companies, and such of them as do not pay the medical practitioner who is at the pains and trouble of examining for them, held up to public odium and reprobation, and that most justly, it affords me great pleasure to bear my humble testimony to the wiser and better, because more just and equitable, course pursued by the following companies—viz., the "London Standard," the "Albion," also London, and the "London Mutual Life and Guarantee Society," of which latter I am the medical referee in this place. I have been employed by all of these companies, and my services moderately, but fairly, rewarded. As a proof of the necessity of insurance companies employing proper medical practitioners, and paying them fairly, I shall merely

call to your recollection a case tried in Dublin some twelve or thirteen years ago, in which the testimony of another physician and myself saved the company £1000; the person insured being in a consumption at the time the medical man (unpaid by the company) gave the certificate, never having felt his pulse, or examined him stethoscopically at all!—*Verbum sat.*

JOHN COLVAN, M.D., F.R.C.S.

Armagh, May 7, 1852.

##### THE "EAGLE."

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—Having been lately in communication with the "Eagle Insurance Company," through their agent, Mr. E. Browne of 2, Fownes's-street, I find this company to be one that "never gives any remuneration to the medical man employed on the part of the party insuring." As you have been of late directing public attention to this subject, may I beg the insertion of the above. I had not for a long time before met with a company acting on this principle.—Yours, &c.,  
May 5, 1852. A SUBSCRIBER.

##### MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

DR. J. F. DUNCAN, interim Treasurer, acknowledges with thanks the receipt of the following sums since last report:—

Dr. Lynn, Markethill	...	1 1 0

Mr. James Black of No. 9, Leinster-street, has been authorized to collect subscriptions in Dublin, and give the necessary receipts.

##### THE PHARMACY BILL—ALARM OF "GENERAL PRACTITIONERS."

I AM much surprised at the apathy which seems to pervade the ranks of the general practitioners, both in London and the provincial towns, respecting the Pharmacy Bill. That measure has been read a second time in the House of Commons, and is now in committee, and, if not strenuously opposed, has every prospect of passing both houses of parliament, and becoming the law of the land. You, sir, are a member of the select committee now sitting on the bill, and I cannot help thinking that you are either deceived as to its probable effects, or that you are not as usual sensitively alive to the interests of the public and of surgeons in general practice. I am strongly of opinion that, should the Pharmacy Bill pass into a law, it will most injuriously affect the public, and seriously interfere with the legal practitioners of medicine. No man knows better than you do the frightful extent to which chemists assume the functions of medical men, and the fearful consequences which result from "counter practice," and even domiciliary visits. The present bill gives full power to the Pharmaceutical Society (already incorporated under a royal charter) to regulate with all the machinery of a royal college the affairs and government of the chemists and druggists of England and Wales; and, not content with this, they wish to assume the same power over the chemists of Scotland. They contend not only for registration, and full power to make such by-laws as they may think proper, without any control, but also for the sole regulation of the education and examination of all their future members. And what is to be the course of their examination? Why, in the classics, in dispensing and prescriptions, in botany, in chemistry, in materia medica, in pharmacy, and in toxicology, which last word may include almost anything pertaining to the practice of medicine. I am rather sur-

prised, indeed, that midwifery was not also included, which some chemists now boldly assume the right of practising. Now, sir, I ask my medical brethren, and I ask you, whether, with these considerable fragments of a medical education, the future race of chemists will not on the strength of their examinations, and a showy diploma placed in their windows, most egregiously deceive themselves as to their amount of medical knowledge, and also sadly deceive the public into a belief that they are perfectly qualified to treat and cure diseases? My firm conviction is, that by the passing of the Pharmacy Bill, "counter practice," and the treatment of diseases by chemists, which now obtain to such an extent, will be increased at least ten-fold; and I look upon the measure as being fraught with great danger to the public, and with great injury to medical men. Even the present race of chemists will, I presume, be entitled under the act to another flaring diploma, and will consider themselves as better qualified by such a licence to pursue their present dangerous career. I do not for a moment mean to charge the more respectable houses in London, and in the larger towns, with resorting to such dangerous practices; and I am convinced that Mr. Jacob Bell, and you, sir, and others, may believe that this bill is calculated to prevent rather than promote the evils of which I complain. I regret that after much consideration of the subject I cannot entertain this view; and I know that many of my medical friends fully agree with me in the opinion which I have thus expressed. It will naturally be asked what remedy I propose? Let me say at once that I would not object to the education of chemists under proper regulations. I simply object to their assumption of functions for which they are not educated. They may dispense the prescriptions of physicians and surgeons, and they may vend all the usual medicines *ad libitum*, except the strong poisons, such as arsenic (already guarded), prussic acid, oxalic acid, opium, and its preparations, chloroform, &c., which ought to have been included in the arsenic bill. I would not prevent their doing anything which belongs legitimately to the trade or business of a chemist, but I would propose that a clause should be introduced into the bill, making it penal for a chemist to prescribe for or treat diseases, or to act in any way as a legally qualified medical practitioner. I would restrict the chemists of this country as the pharmacians of France, and other parts of the continent, are restricted; and I would despise the mandarin nonsense respecting "the liberty of the subject in this free country," and would consider that as salutary and requisite which should evidently prevent the destruction of life or health. If Mr. Jacob Bell should object to such a clause, I would call on you, sir, and on my medical brethren, to oppose the Pharmacy Bill by every means within their reach. There are other objections to the bill, such as its inappropriateness pending a general measure of medical reform. I object also to the creation of a new corporation with parliamentary powers, when, in fact, the chemists ought to be joined to the Society of Apothecaries, whose present functions (which they are seriously neglecting if they assent to the Pharmacy Bill) must soon necessarily cease. But your space and my time are both exhausted.—*Dr. Webster of Duwich to the Editor of the Lancet.*

## MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The Annual Distribution of the Funds at the disposal of the Society will take place on the first Monday in June.

Applications for assistance must be made by printed forms, to be obtained from the Honorary Secretaries, and must be sent in to the Branch Associations before the 6th of May, or to the Parent Society before the 10th of May.

Branches are established in the principal towns of Ireland, and with Honorary Secretaries, as follows:—

Armagh, Dr. Colvan; Belfast, Dr. Stewart; Cork, Dr. Lloyd; Newry, Dr. Erskine; Waterford, Dr. Carroll.

The applications are to be forwarded to the Secretary of the nearest Branch, if any be near, or to the Secretaries of the Parent Society in Dublin.

Subscribers to the Parent Society are requested to send in their contributions as soon as possible to the Treasurer, Dr. Duncan, 19, Gardiner's-place, Dublin; and subscribers to the Branch Associations, to the Local Treasurers respectively.

By Order, Wm. Kingsley,  
Chas. Benson,  
Hon. Secs. Parent Society.

Royal College of Surgeons, Dublin, April, 1852.

THE ROYAL MEDICAL HALL,  
64, DAME-STREET, DUBLIN.

Change of Proprietorship.

BEWLEY, OWEN, AND CO., APOTHECARIES,  
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of  
THE ROYAL MEDICAL HALL,  
beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING  
OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT  
embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

\* \* GENUINE COD-LIVER OIL,  
of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT  
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention*; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Just published, Second Edition, with many additions and new Plates, 8vo, cloth, 16s.,

### ON DISEASES OF THE LIVER.

By GEORGE BUDD, M.D., F.R.S.,  
Professor of Medicine in King's College, London.  
London: John Churchill, Princes-street, Soho.

Just published, Fourth Edition, revised and enlarged,  
8vo, cloth, 10s. 6d.,

### ON DISEASES OF THE BLADDER AND PROSTATE GLAND.

By WILLIAM COULSON, Surgeon to St. Mary's Hospital.

"Mr. Coulson's work presents a clear, well-arranged, well-selected *resumé* of the labours of others, interspersed with so much of his own observations and opinions as show him to be practically conversant with the diseases of which he treats; the fourth edition is carefully brought up to the present advanced state of our knowledge on the subject."—*Dublin Quarterly Journal*.

"The practical and comprehensive character of Mr. Coulson's volume claims for it a place in the library of every surgeon who desires to be on a level with modern improvements."—*London Journal of Medicine*.

London: John Churchill, Princes-street, Soho.

Just published, Second Edition, 8vo, cloth, 20s., or with Coloured Plates, 30s.,

### ON DISEASES OF THE URINARY AND GENITIVE ORGANS (IN BOTH SEXES).

Part I. Non-specific Diseases. Part II. Syphilis.

By WILLIAM ACTON,

Late Surgeon to the Islington Dispensary.

"Mr. Acton's work must be diligently studied by every practitioner who would desire to benefit, instead of injuring, his patient; it has a distinctive and preëminently diagnostic value."—*Medical Gazette*.

"The present edition of Mr. Acton's work is much enlarged, and contains a most valuable collection of matter."—*Lancet*.

London: John Churchill, Princes-street, Soho.

Foolscap 8vo, cloth, 12s. 6d.,

A MANUAL OF THE PRINCIPLES AND PRACTICE OF OPHTHALMIC MEDICINE AND SURGERY; illustrated with 102 Engravings, plain and coloured.

By WHARTON JONES, F.R.S.,  
Professor of Ophthalmic Medicine and Surgery in University College, London.

"The work presents, in a compendious form, a complete and correct view of the present state of ophthalmological science, and, as such, we strongly recommend it to the attention of professional readers."—*Edinburgh Medical and Surgical Journal*.

"We can assure students, that they cannot meet with a hand-book on this subject that is more ably or more carefully written."—*Medical Gazette*.

"We entertain little doubt, that this work will become a manual for daily reference and consultation by the student and general practitioner."—*British and Foreign Medical Review*.

London: John Churchill, Princes-street, Soho.

Just published, Eleventh Edition, 12mo, cloth, 10s.,  
DR. STEGGALL'S MEDICAL MANUAL FOR APOTHECARIES' HALL, and all other Medical Boards.

This Edition will be in accordance with the New London Pharmacopœia, and contain great additions.

London: John Churchill, Princes-street, Soho.

### COMPLETION OF DR. MURPHY'S MIDWIFERY.

One Vol. 8vo, cloth, with many Illustrations, price 16s.,  
LECTURES ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.

By EDWARD MURPHY, A.M., M.D.,  
Professor of Midwifery in University College, London.

"The 'Lectures on Preternatural and Complex Labours and Lactation' are Sold separately (price 7s. 6d.) for the convenience of those who have purchased the 'Lectures on Natural and Difficult Parturition.'"

London: Taylor, Walton, and Maberly, 28, Upper Gower-street, and 27, Ivy-lane.

### SCHOOL OF SURGERY.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Summer Courses of Lectures commenced on Monday, the 26th of April, when Lectures on the following subjects were delivered, in accordance with the regulation of the Council of the College:—

Materia Medica	...	Dr. Williams.
Medical Jurisprudence	...	Dr. Geoghegan.
Practical Chemistry	...	Dr. Barker.
Botany	...	Dr. A. Mitchell.

Examinations will be held, and Premiums awarded to the successful Candidates, at the termination of the Session.

### DISEASES OF THE EYE.

#### SUMMER SESSION.

DOCTOR JACOB will commence his Lectures on DISEASES of the EYE, in the City of Dublin Hospital, on Tuesday, the 18th of May, and will continue them during the SUMMER SESSION, so as to form a complete Course of OPHTHALMIC SURGERY.

#### CITY OF DUBLIN HOSPITAL.

The Summer Session commenced on Monday, the 26th of April, and Gentlemen who have not yet entered are requested to do so on or before the 17th inst., as on the following day Dr. JACOB will commence his Lectures on DISEASES of the EYE in the Theatre of the Hospital at Four o'clock p.m.

This Hospital is visited daily at nine o'clock, and the Clinical Lectures and other Instruction regularly continued, as during the Winter Session.

By a recent Ordinance of the Royal College of Surgeons, separate Certificates of Hospital attendance, during the Summer Session, are required.

For further particulars, apply to C. Benson, Esq., M.D., Secretary, 34, York-street, or at the Hospital.

#### CITY OF DUBLIN HOSPITAL.

THE HOUSE-SURGEONCY of this Hospital will be vacant upon the 25th inst., when the Election of a Gentleman to fill the Office will take place.

Candidates must have received the whole, or a portion of their Education, in the Hospital, and a preference will be given to such as are Licentiates of the Royal College of Surgeons in Ireland.

Application, with testimonials, to be made to the Secretary, Dr. Benson, York-street, Dublin, on or before the 24th inst.

#### THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin.  
London: John Churchill, 46, Princes-street, Soho.

Wednesday, May 12, 1852.

CASE OF RETENTION OF URINE—FALSE PASSAGE—HÆMORRHAGE INTO BLADDER, ETC.

By ROBERT LYNN, A.B., M.D., F.R.C.S., of Sligo.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—The accompanying case may, I think, be read with interest in connexion with the discussion on "Retention of Urine" which took place at the Royal Medical and Chirurgical Society, as reported in last week's MEDICAL PRESS.—I am very truly yours,  
ROBERT LYNN.  
Sligo, May 13, 1852.

Mr. W——, ætat. 74, was attacked, February 17, after exposure to cold, with retention of urine. His medical attendant, on the 18th and morning of the 19th, made frequent but unsuccessful attempts to introduce a catheter; and on the 19th, at two o'clock, when called to see him, I found him in extreme suffering, the bladder greatly distended, the floor and his linen covered with blood, anxiously calling for help, and "willing to bear anything at my hands." Taking a full-sized catheter, I endeavoured to introduce it, but at the junction of the penis with the pubis, I found the point turning aside to the right, and entering a false passage. All my efforts to keep the instrument (and I tried them of all sizes) from entering this passage were fruitless, and I thought it better to desist for the present, gave the patient a large opiate, and promised to see him again in two hours.

At six p.m., I again called on Mr. W——, he had got some sleep (the first for two nights) from the opiate, was in better spirits, and willing to bear patiently any pain I might put him to. After the previous unavailing attempts, I had not much hope of relieving him by the catheter; but after a few gentle trials, I was much gratified to find that the point of the instrument *evaded* the false passage, and then with the greatest facility passed on to the bladder. I left the instrument in for the night, and on the 20th, 21st, and 22nd, had not the *slightest difficulty* in introducing the instrument twice and sometimes three times daily.

On the morning of the 23rd, having been unavoidably

VOL. XXVII.

absent longer than usual, an attempt was made to introduce the catheter, which must have again opened the false passage, as on my *now* endeavouring to pass the instrument, I found the point turn aside as on my first seeing him, in defiance of every effort. In the course of this day and the 24th, I made frequent attempts, and my friends Drs. Homan and Tucker, who were kind enough to see the patient with me, also tried the introduction of the instrument, but without success. The instrument *would* turn to the right, and would come out full of blood.

On the 26th, the symptoms became so urgent—rigors, cold perspirations, vomiting, &c.—that I urged the opening of the bladder, either above the pubis or by the rectum. The patient, although willing to bear any pain the catheter might produce, would not hear of any other operation; said he had made up his mind for death, and was thankful for the few days relief, "which had given him time to make arrangements for eternity." I was unwilling, however, to leave him without another effort, and I said to Dr. Tucker, who was present with me, "that having passed a catheter so frequently in the case, I thought I could guide it through the false passage, and force my way into the bladder without adding to the danger." Accordingly, I took a No. 6 silver catheter, and slowly and steadily forced it on until it reached the bladder. Although no urine followed, still, from the sensations conveyed to my hand by the instrument, I felt confident it was in the bladder; I also felt confident that I had kept close to the natural passage; I concluded the instrument was clogged with blood, so taking a No. 12, with a gum-elastic inside, I passed it without difficulty into the bladder, and on withdrawing the gum-elastic, a gush of urine followed. From this date until the 29th, the patient went on favourably; the instrument was introduced twice daily; the urine became free from any tinge of blood, and the constitution seemed to suffer very little from the violence done to the urethra. About two o'clock of this day, however, while straining at stool, and passing some exceedingly hard and bulky excrement, he got suddenly faint, covered with cold perspiration, and the bladder filled up almost imme-

diately, causing a renewal of his worst suffering. His friends thought he was dying, but I was not able to see him until six o'clock. The bloodless look of the patient, and the firm unyielding feel of the enormously distended bladder, at once told me that it was full of coagulated blood, and that I had another danger to contend with. I immediately passed a catheter, but although I moved it about freely in the bladder, in the endeavour to break up the clot, and to get at the most fluid part, I failed in affording any relief.

March 1st. I had very little better success.

2nd. I made a stilet by lengthening out a spiral spring, in hopes that by rotating and occasionally withdrawing it, I might be able to remove the clots that in succession entered the catheter, and so by degrees empty the bladder. I found this very useful, and at my morning visit, with the longest instrument I could get, and the point elevated as much as possible, urine mixed with blood began to flow; and at twelve o'clock, in presence of my friend Dr. O'Farrell of Boyle, who happened to be in Sligo, I was able to get off a still larger quantity, and to reduce the tumour to at least one half. In the evening the tumour became still less, and from this date the case went on favourably; the patient gradually regained the power over the bladder, and has been able to walk to my house once or twice to have the catheter passed, so as to guard against the closure of the new passage.

There are many points of interest in this case. The false passage commencing so short a distance from the orifice, the great difficulty in avoiding it, the little constitutional disturbance caused by the tunnelling of a new passage, the occurrence of the hæmorrhage, &c., many days after, the use of the spiral stilet: I scarcely think any syringing would have been so effectual, &c., but I have no time for further remarks.

##### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

###### REMARKS ON HYDROPHOBIA.

By B. E. BRODHURST, M.R.C.S.

THE author observed that it was to *hydrophobia rabiosa*, or that disease which arose from inoculation with the saliva of a rabid animal, in contradistinction to *hydrophobia simplex*, that he was desirous of directing attention. Hydrophobia was a disease properly of the canine race, and did not arise spontaneously in man; but it was communicable to him from all rabid animals. There was no instance on record of the disease being communicated from man to man, although experiment proved that it could be transmitted from man to animals. There appeared to be a peculiar predisposition in the canine race to this disease. The author was inclined to believe that the disease occasionally arose spontaneously in the dog, although Mr. Youatt had expressed a contrary opinion, to the effect that it was propagated by inoculation alone. The author was led to the opinion opposed to that of Mr. Youatt by observing that rabies was extremely rare in the south of Europe among the native dogs, but that it was by no means an unfrequent occurrence for an English dog to become rabid when taken to the south. The author considered that diet exercised a marked influence; that if a dog be allowed a diet principally of animal matter during the summer, he would almost certainly die hydrophobic. This applied equally to English and natives dogs. Extreme cold and privation, however, also favoured the development of the disease, and seemed to be the most frequent cause of the malady among wolves. The author then proceeded to detail the more prominent symptoms produced on man by the bite of a rabid animal, as well as the periods within which they were usually developed. The wound healed without any peculiar indications, just as a similar bite by a healthy animal would heal; but at some uncertain period, often extending to forty or sixty days, pain was felt in the course of the nerves of the limb, and might be taken as the first positive indication of the approach of hydrophobia. Dis-

turbance of the general health sometimes preceded this stage; the cicatrized wound became a sore. General nervous irritability and other manifestations of cerebral disorder, with mental emotions of fear and unnecessary dread on the approach of persons; hallucinations, spectral illusions, inordinate and disordered sensibility of the skin, with morbid increase of acuteness in the organs of special sense, were among the most characteristic signs of the confirmed disease. The author, who had witnessed three cases of hydrophobia, proceeded to relate the particulars of one which occurred in Vienna to a man aged 64, a farrier, who was bitten in the palm. The wound healed, and it was not till the forty second day from the injury, after a debauch, that the patient awoke feverish, and with an aversion to water. He was removed to the hospital, under Professor Schulz. Various remedies were tried: cantharis, opium, belladonna. Tetanic spasms, of which opisthotonos was the expressive feature, came on. The convulsions continued, and, agitated with emotions of intense fear, he died. The body was examined by Rokitansky. The membranes, as well as the substance of the brain, were congested; the arachnoid opalescent; the bronchial and pulmonary mucous surfaces deeply congested; and the lungs remarkably engorged. The heart was empty, and the blood was fluid in the vessels; the mucous membrane of the kidneys and ureters congested. The bladder was pale, and all the other viscera healthy. The author stated that the characteristic morbid appearance in the dog was an injected condition of the medulla oblongata and its membranes. But Rokitansky had stated, at the time of the above examination, that of the many cases he had examined, he had never found any appearances in the medulla oblongata which he could connect with the spasm. The author then directed attention to the *certainty* of the action of the saliva of a rabid animal when once introduced into the blood: not less certain, indeed, than that of a venomous serpent, though the period of its incubation was much longer. Although he admitted that one-third of those bitten might not manifest any symptoms, whereas the bite of a poisonous reptile was immediately followed by palpable effects, yet this immunity might be explained by the virus being wiped from the tooth before it penetrated, in the bite of a dog; while in a serpent the venom only exudes when the mandibular pressure ceases to be made. The author believed, that in hydrophobia was primarily a blood disease, the presence of another blood disease, such as syphilis or variola, might arrest the hydrophobic poison. He regarded it as proved beyond doubt that symptoms of hydrophobia had been arrested and suspended by variola; for hydrophobia could only develop itself after another poison, that might have been present at the period of inoculation, should have run its course. He rejected the doctrine that the rabid poison could lie in a wound, and neither irritate nor be absorbed. It had been stated by writers that the period of recrudescence was the commencement of the malady, the period of delitescence being overlooked. It was thus supposed that the poison could lurk in the wound, and that it was capable of being removed by excision at any time prior to the state of recrudescence. This disease, once developed, appeared necessarily fatal; treatment therefore, to be effectual, should be vigorous and energetic in the primary or preventive period; and the author conceived, that in variola its course might be retarded and its intensity modified by substituting another poison, which had a certain affinity for the blood, so might it be hoped that the hydrophobic poison might be rendered amenable to medical aid through the agency of mineral or animal matter. He mentioned the powerful effects on the blood of arsenic and mercury, and thought that one or other of these remedies, administered *ab initio*, might be productive of happy results. The author referred to the successful cases recorded by Wendt in the Breslau Hospital, where salivation appeared to have been practised with success, and where means were also used to remove the virus locally from the wound. The author, in conclusion, considered that the patient should remain under active treatment in every case

from forty to sixty days; the influence of the mineral should be rapidly obtained and continued, so that a positive change might be effected in the blood, and the condition which favoured the hydrophobic virus destroyed.

Dr. WEBSTER coincided with the author respecting the greater frequency of hydrophobia in cold, compared with warm climates. In the north of Europe this disease was much more prevalent than throughout Italy or France. In northern Germany, especially Prussia, he (Dr. W.) could speak from his own knowledge—acquired when residing at Berlin—as to the marked ravages it produced in that country, which medical men chiefly ascribed to famished wolves coming from the forests of Poland during severe winters, and biting village dogs, that afterwards spread the malady. Mr. Brodhurst had alluded to an outbreak of this terrible scourge in Stockholm last winter, and he would also state that, about the beginning of the current year, it prevailed like an epidemic in Altona and Hamburg, besides several places in Holstein, whereby a number of persons died; whilst cows and horses, but particularly the latter, were often attacked. Although less common in warm regions, the complaint prevailed at times in those latitudes; and he might mention that, whilst travelling in Italy many years ago, several fatal cases occurred, one being a priest, who was bitten by a goat. Further, hydrophobia was very common last February in the department of the lower Loire—of which Nantes is the chief town—amongst dogs, cats, and cows. Besides such facts, only that morning the newspapers reported the case of a physician practising at Valence, on the Rhone, who died from hydrophobia early in this month. Contrasted with these statements, indicating considerable prevalence of canine madness on the continent, it becomes highly satisfactory to find the disease was now much more rare in London than formerly, only two fatal examples having appeared since 1846 throughout the whole metropolis, whereas sixteen deaths were recorded during the seven previous years. This recent remarkable immunity, he thought, may be justly attributed to Mr. Fox Maule's act, which interdicted dogs being employed in drawing carts, whereby hydrophobia was said to be often produced in these animals. Mr. Brodhurst's notion of the blood becoming vitiated by the absorption of hydrophobic virus was not altogether new, although his recommendation of mercury, in order to counteract its deleterious influence, appeared more novel. For instance, a Polish physician—Dr. Czajewski—read an interesting paper before the medical section of the scientific Congress of France, which assembled at Orleans last autumn, advocating somewhat similar views; but the treatment he employed was very different. That authority advised copious bleedings every four or five days, until deliquium followed, so that before any serious symptoms supervened, all morbid taint being eliminated from the patient's blood, recovery might be more confidently anticipated. Notwithstanding various specifics for this incurable disease have been occasionally vaunted, none ever stood the test of experience, whether it was by excising the sublingual gland, reported some years ago as beneficial in Russia, or the vegetable discovered by a French traveller in Abyssinia, but now forgotten. After making one or two additional remarks, Dr. Webster said, in conclusion, having seen three fatal cases of hydrophobia, and believing every kind of treatment hitherto employed has proved utterly inefficacious, he therefore considered the author's proposal of administering mercury in order to neutralize the poison deserved consideration.

Mr. M. HENRY inquired the experience of the members of the Society as to the time when the disease developed itself after the reception of the poison? Some of the accounts having reference to this matter appeared almost fabulous.

Dr. JAMES BIRD had seen only two cases of the disease, and these occurred in Bombay. One of the persons affected was a Sepoy, a stout, muscular man; the other was an English officer. The first was affected with the disease twelve months, the other six weeks, after having been bitten. In

the case of the Sepoy, the bitten part appeared to be affected with neuritis. There was a little tubercle at the cicatrix, which, when touched, threw the patient into convulsions. Mercury, given to pytalism, appeared to relieve the violence of the symptoms, but it was administered in conjunction with enemata of tobacco, and hence it was difficult to determine to which agent the relief of the spasms was to be referred. He died at the end of six or seven days. The officer died on the third or fourth day.

Dr. THEOPHILUS THOMPSON recollected a case which had been mentioned to him by the late Mr. Hunter of Islington, of a servant girl who had been bitten by a rabid animal. The symptoms of hydrophobia developed themselves a week afterwards. An effect similar to that observed in Dr. Bird's case was produced by touching the cicatrix, the girl becoming immediately convulsed. An incision through the skin was made round the cicatrix, and then pressure exerted no injurious influence. She died ultimately of the disease. This case, as well as that of Dr. Bird, was rather unfavourable to the theory of the disease being dependent upon a morbid condition of the blood. Mr. Youatt had placed much confidence in the administration of a mixture of belladonna with scutellaris, as a preventative of the disease in dogs, after they had been bitten by a rabid animal. Mr. Youatt had made an extensive series of experiments with this mixture, and the result had convinced him that it had some prophylactic power. With respect to the theory of the disease being dependent upon an altered condition of the blood, he might mention a certain train of symptoms, which resulted from the bite of a cat not in a rabid state. These consisted of wasting of the muscles, contraction, spasm, and neuralgia. There was enough of analogy in these two conditions to show an argument against the blood theory, as they showed a more local cause to be at work.

Mr. HODGSON had seen the case of a poor man, some years since, affected with hydrophobia, who had taken belladonna to a great extent without any beneficial effect. There were one or two points in the paper which gave rise to interesting suggestions. 1st. Was the disease as invariably fatal in the dog as the man? He had some years since, made inquiries upon this point amongst the keepers of fox-hounds, veterinary surgeons, and others likely to be well informed on the matter. All of these agreed, that when attacked with hydrophobia the dogs invariably died. They all died also within a fortnight of the time of the accession of the symptoms. This was an important circumstance, because it was considered that if a person were bitten by a dog supposed to be rabid, the circumstance of the dog's living beyond the fortnight was regarded as an evidence of the safety of the bitten person. There was another practical point in the paper to which he would refer. He had seen a case some years since, which seemed to show that excision of the bitten part, at any time previous to the accession of the disease, would prevent its occurrence. A rabid dog bit two children, and afterwards their father in his bare arm. One child was bitten in the leg, the other in the shoulder; all slightly. The child that was bitten second was seized with hydrophobia. After this the father and the other child had the parts excised. They remained free from the disease. This fact was important so far as it went; it would be observed that the middle one bitten died, so that the dog must have been mad when it bit the third person. In all the inquiries he had made in reference to the effect of excision of the bitten parts, he could not hear of a single instance in which the disease had appeared in a bitten person after the above precaution had been taken.

Dr. T. THOMPSON wished to explain that in Mr. Youatt's case the belladonna had been given as a prophylactic and not as a curative agent. Two persons who had been bitten by the same dog as the servant at Islington, whose case he had referred to, had had the parts excised a considerable time after being bitten; they escaped. The servant girl would not submit to such a proceeding, and suffered from the disease.—*Lancet*.

## CASE OF ILEUS WITH LONG-CONTINUED OBSTRUCTION.

By JOHN SODEN, Esq., F.R.C.S.,  
Surgeon to the Bath General Hospital.

(Read at the Quarterly Meeting of the Bath and Bristol Branch of the Provincial Association.)

THE subject of the following case is a gentleman aged 63, short in stature, of a nervous sanguine temperament, and of active and extremely temperate habits. For the last twenty years he has enjoyed uninterrupted good health; he had previously suffered from the effects of hot climate in the West Indies.

On October 16, 1851, feeling indisposed, and for a short time previously his digestion having been out of order, he took an active aperient. It affected him with unusual severity, continuing in operation till the morning of the following day. He was then sufficiently well to occupy himself in his garden, where he was sometimes engaged standing about and assisting in planting. At dinner he ate a small quantity of meat. Soon afterwards he was seized with violent spasmodic pain in the abdomen. He took a large dose of castor oil with a few drops of laudanum, but ineffectually; an emetic of ipecacuanha was then tried with no better result. There was no disposition to sickness and the emetic action was not easily induced. An enema of warm water and a warm hip-bath were next had recourse to, but with no immediate relief. Towards evening, however, he became gradually better, and passed a tolerable night. On the following morning the pain returned with the same severity, and I then saw him for the first time.

This was on the 18th. I found my patient in an alarming condition. There was now frequent vomiting, the matters ejected being of a dark colour and very offensive, as was also the breath.

The attacks of spasm were intense; there was an anxious expression of countenance, and prostration of the nervous power seemed already impending. On examination there was a general sense of tenderness about the umbilicus, and chiefly on the left side, attended in this position by marked dulness on percussion; however, neither the dulness nor the tenderness were sufficiently circumscribed to indicate the precise seat of the constriction, supposing such to exist. I should mention that the patient was the subject of an inguinal hernia, and that in spite of the large dose of oil (one ounce) that had been administered, there had been no passage from the bowels since the commencement of the attack. Uncertain whether I had to deal with an internal hernia or an attack of ileus, I at once determined to abstain from all aperient medicine, and I prescribed small doses of calomel and opium to be administered every two hours. Mustard poultices, and such other local means were used as seemed to afford alleviation. In the evening he was no better, and the ejections were now of a most suspicious appearance. I directed the pills to be continued, with an increased quantity of opium. I was also induced to try the effect of a turpentine enema. 19th. There is no amendment, but rather an aggravation of the symptoms, with the addition of hiccough. The enema was retained for some time, but returned unmixed with fæces, and without producing any sensible effect. The matters vomited are now purely fecal. The countenance is more sunk, the prostration very great, and the case presents altogether the worst possible aspect.

I felt that there was nothing more to be done in the way of active means, and that it would not be prudent to carry the mercurial action further, though the pills had appeared to agree in invariably prolonging after each dose the interval from spasm and vomiting. I now purposed to administer one more opiate without the calomel, and then to strictly follow out the expectant course of treatment, not allowing anything to go into the stomach, and to abide the issue. I should mention, that early in the morning I had made another trial with the injection. I passed a long flexible tube into the bowel, to the extent of about twelve

inches, and threw up as much warm water as the patient could bear, trusting, that if the disease arose from any mechanical cause, some relief might be afforded by this measure. The operation was effected without any difficulty or distress to the patient beyond the inconvenience of the distension of the bowel, but no result ensued; the water came away perfectly clear.

Before putting in force the plan of treatment I have indicated, I requested a consultation, and Mr. Gore was called in. Mr. Gore saw the patient with me between two and three p.m., nearly forty-eight hours from the commencement of the attack. He entertained a most unfavourable view of the case; his impression was against the idea of an internal strangulation from a mechanical cause, and he rather considered that the symptoms indicated an inflammatory state, of a low type, of some portion of the bowel, but that any opinion on the point could only be speculative and most uncertain.

Up to this moment there had been no reaction of a febrile character; the skin had remained cool throughout; the pulse very low but not rapid; the general symptoms had been those of a steadily progressing exhaustion. The powers were so low and the disposition to sickness so frequent, that Mr. Gore thought the effect of the opiate I had proposed would be doubtful, and that the safer course would be to follow out the expectant plan, without its administration. He also suggested that a drop of Scheele's prussic acid should be occasionally administered, and that instead of cooling the mouth from time to time with cold liquids, the patient should be permitted to suck a lump of cold ice. 20th. On visiting my patient early this morning, I was glad to find him still alive and apparently in much the same state. The ice was most grateful to him, and he also found a soothing influence from the prussic acid. Whether it was really of any use, or whether the pleasurable sensation was attributable to the teaspoonful of cold water in which it was exhibited, I could not determine. The vomiting continues at the same intervals; it is much less in quantity, from the empty condition in which the stomach has been kept, but still stercoraceous. The spasms have decidedly abated both in frequency and force. The same treatment to be steadily continued. 21st. The vomiting has not been stercoraceous since last evening; the symptoms are all materially lessened, but great exhaustion is present. Seven p.m. Great restlessness; voice weak and husky; throwing about of the arms. With these warnings I considered it absolutely necessary to administer some nourishment, and I commenced with a little barley-water and gruel. 22nd. No return of vomiting; the small quantity of gruel taken has been borne, and the patient is not weaker to-day. 23rd. Scarcely anything was swallowed yesterday; this morning's report is still favourable as far as relates to the local symptoms, and the abdomen, which has never been inordinately distended, is now perfectly flat; the signs of increasing debility are again more evident, and in addition, there is some excitement of the head, heat and flushing, with a disposition to be talkative, verging on delirium. A very few teaspoonfuls of chicken broth to be occasionally administered. 24th. Much the same; the same plan to be continued. 25th. The excitement continues rather distressingly, with craving for food, and for some hours broth and arrowroot have been taken much more freely; the consequence is, fulness in the epigastrium, sense of sickness, and return of pain. It is evident that nothing can pass through the bowel. 26th. To my surprise the patient is much improved this morning; free vomiting, which is not stercoraceous, has relieved the distress of yesterday; he is calm, and free from pain, but greatly exhausted. He is now sufficiently collected to be made aware of the importance of his abstaining from every kind of food, and with great resolution is determined to submit to that privation, or to any other treatment that may be proposed. The only chance seems to be to support life by injections. The plan has not hitherto been adopted, from the patient's excited condition, and his strong objection on account of painful piles, and a difficulty that he

is now experiencing in passing water, and for the last few days he has not been in a state to be reasoned with on the subject. Half a pint of strong beef-tea, with four drops of laudanum, to be administered per anum, twice or three times a day. The ice and prussic acid, which are still very grateful, to be continued. 30th. The injections have been regularly administered, and have answered admirably; they have never returned. There has been neither pain nor sickness, and the small quantity of laudanum appears to have exerted a general soothing influence. The patient's aspect is improved, and in point of strength he does not lose ground, though the rule of abstinence has been rigidly maintained. There is also further evidence of amendment, if it may be trusted. At six o'clock this morning the bowels were moved for the first time from the commencement of the attack, on the 17th of October, thirteen days ago; the stool is liquid, small in quantity, and healthy in appearance. The treatment to be continued.

November 1st. The bowels have again acted this morning, and the character of the evacuation leaves no doubt that it cannot have been merely the accumulated contents of the rectum from the injections.

From this date the case was straightforward. The utmost caution was pursued in the administration of food, and no relapse interfered with a gradual and progressive convalescence.

The attention of the profession has latterly been much directed towards cases of this description, with a view to their relief by operative means, where the symptoms appear to depend on mechanical causes. It would be a great boon if some clear diagnostic sign of distinction could be shown to exist between the effects of an internal strangulation, and the paralysis induced in its functions by an inflamed condition of a portion of the bowel. I fear the case I have just read will not tend to elucidate this difficulty. From reviewing the history of my patient's malady, I am totally at a loss to say in what it differs from those of persons in whom some accidental stricture was proved to exist. In cases of the latter kind the pain and tenderness may sometimes be more definite, but this is by no means a rule. There is nothing to be observed in the more tardy or violent onset of the symptoms; in both they come on with equal violence, and with equally rapid effect upon the powers of life. In both there is the permanence of the prostration so long as the bowel is impervious, and the continued absence of reactionary fever. Trace the individual signs, the flatulence, the character of the spasms, the hiccough, the stercoraceous vomiting, &c., and the analogy becomes only the more complete.

I have, therefore, I regret to say, no other practical deduction to bring forward than the testimony this case affords, of the favourable result that sometimes attends the resources of Nature in cases of intestinal obstruction where Art is of no avail.—*Prov. Journal.*

#### INUTILITY OF THE ABDOMINAL BANDAGE AFTER PARTURITION.

(Being Part of a Lecture delivered this Session at the St. Lawrence School of Medicine, Montreal.)

By F. C. T. ARNOLDI, M.D.

HAVING now told you all the essential points to be rigidly attended to during the process of labour, you must be made as familiarly acquainted with the nursing part of the puerperal state. The child having been disconnected from the mother, and the placenta withdrawn, your next care should be that the uterus has assumed a state of permanent contraction, and for this purpose you should diligently watch for at least half an hour, because very alarming symptoms may supervene, such as uterine hæmorrhage, syncope, or convulsions. The most common is uterine hæmorrhage. This may take place under various circumstances, but the most ordinary is an atonic state of the uterus. The cause of this condition may either be immediate or remote—that is to say, immediately after delivery the uterus may cease to contract, or having, to all appear-

ances, permanently contracted, it may relax, get into the atonic condition, and so give rise to profuse hæmorrhagic discharge. Now this discharge, in both instances, is owing to the *baillaut* condition of the uterine venous sinuses; fortunately, however, this is not an everyday occurrence, yet apparently, with a view of anticipating such a serious misfortune, our ancestors and modern authors lay down strict injunctions for the application of an abdominal roller or bandage. There was a time when I would have thought it almost sacrilegious to have acted in contravention to this precept, but a case happened to come under my charge in which I was very much interested, and which gave rise to close anatomical investigation on my part. I shall narrate it to you in a familiar manner, and show you the conclusions I came to:—Mrs. A— was confined on the 14th of August, 1830. Being a primipara, it was as usual a painful and somewhat tedious case, but on the whole, nothing uncommon. The secretion of milk set in within fifty-four hours, and nothing appeared to indicate the prohibition to her sitting up in an arm-chair on the fourth day for the purpose of having her bed made. The bandage had been applied round the abdomen according to orthodox rules. On the evening of the fourth day, she complained bitterly of pains in her loins and continual bearing-down pains. Supposing that the bandage had not been applied sufficiently tight, it was drawn a little tighter, but instead of affording any relief the pains were increased. It then struck me that as the bowels were in good order, the bandage was the sole cause of the evil, and to satisfy myself I examined a skeleton very attentively, and I came to the conclusion that my notion was correct; in proof only look at this skeleton, and observe the very obtuse angle the brim of the pelvis bears to the axis of the spinal column. You see that the promontory of the sacrum is several inches above the horizontal line of the pubis, that the promontory projects forwards, the sacrum recedes, and thereby forms a recipient cavity. Again, remark the lateral configuration of the skeleton, and you perceive that the great projecting *alæ ilii*, the crests of which are on a line almost parallel with the promontory of the sacrum, form the point from which the tapering figure starts upwards towards what is called the waist. This, you see, is perfectly demonstrable even on the skeleton, how much more so it is, as you must have observed, on the soft subject? Well, having satisfied myself on these two points, I first of all came to the conclusion, that no well-formed woman could keep an abdominal bandage in its proper place, unless indeed it were very tightly put on, and then I inferred that if very tightly put on, it must act very detrimentally on the yet heavy uterus. The bandage, you see, to keep its place, so as to act upon the uterus, must be applied over the hip, otherwise it must act upon the abdominal viscera, and make them press down upon the uterus, in which case the bandage necessarily slips up to the small diameter of the waist, and can no longer carry out the original object intended, and proves a sore annoyance to your patient, who, believing there is some charm in it, keeps herself in a constant fidget by pulling it down, and pulling it, as she believes, into the right place. Now, this of itself gives rise to much unnecessary muscular exertion. If the bandage be kept tight over the hips, it must necessarily act upon the uterus, and that in two ways: presuming it, in the first place, to be necessary, it must be for the purpose of exciting the uterus to contraction, or it must be for the purpose of arresting uterine hæmorrhage; but I maintain that it can produce neither the one nor the other effect: in the first place, it mechanically presses the yet heavy uterus into the bottom of the sacrum (which affords it every facility to descend), and thereby lays the first seeds for prolapsus uteri; and in the second place, if uterine hæmorrhage do supervene, it is one of the most fallacious resorts you can trust to, but further I will tell you when I come upon that subject. To come back to my case: Mrs. A—, as I told you before, suffered much from bearing-down pains on the fourth day, and I may now add, she continued to do so for many months after. Time rolled on, and still

the pains continued, until fortunately she again got in the family-way, but even then, and for the four first months, she was constantly threatened with a miscarriage. She, however, had the good luck to go on to her full time. I delivered her the second time, and determined not to use the bandage again, in lieu of which, as a matter of precaution, I exacted a little more bed rest. My orders were strictly attended to, and her recovery was all that could be wished for. From that day to this, she has had no recurrence of bearing down pains after her confinements, though similarly treated, notwithstanding her having had ten more children, making twelve in all. Since my experience in this case, which was in 1832 (her second confinement), I have never applied the abdominal bandage in my private or hospital practice; I have never met with any sinister results from its omission; and I know of other medical men who have often followed my example equally satisfactorily. Uterine hæmorrhage is the great bugbear, and certainly it is a most serious concomitant, but when it does take place, I can assure you your patient would be badly off, if you had nothing else to trust to but the abdominal bandage. Obesity, or the becoming (to use vulgar parlance) "pot-bellied," is the next argument used against the omission of the bandage; but I can assure you that in the whole of my practice I cannot trace one single instance to such a cause. Hear what a lady writes to me from Quebec: "Dear Doctor,—I was confined on —, and I determined on following your instructions to the letter. My physician and nurse thought I was mad, nevertheless I maintained my point, and certainly I have every reason to be grateful to you; for besides having made a much more favourable recovery than usual, I have been relieved of that horrible annoyance—the belly-band; and the bearing-down pains have not returned." Again, let us look at the puerperal state in a strictly pathological and physiological point of view. Is not parturition strictly and simply a natural and healthy process? Certainly it is, except under casual circumstances. Can the distension of the abdomen from utero gestation be compared with the abdominal distension from ascites? No. In the one instance you have a healthy tonic; in the other, you have one of the worst forms of unhealthy atonic action; in the one, you have a fixed duration, at the end of which tonic muscular contraction sets in, and the abdominal parietes resume their normal condition; in the other, the letting out of the fluid by the trocar is followed by a mere collapse of the abdominal parietes, so that the capacity of the abdomen would still remain the same unless a roller bandage were applied. Were I now speaking of uterine hæmorrhage, I would point out to you how thoroughly insufficient the abdominal bandage alone would be: at any rate, I would show you how much you would be mistaken, if, under such circumstances, you trusted to it as your mainstay. Talking of uterine hæmorrhage, it is a very singular fact, that during a practice of twenty-five years I have never met with more than one case, except such as I have seen in consultation, and of that case I was forewarned, as my patient had suffered from it on three former occasions. Notwithstanding, gentlemen, what I have told you as the result of my own practice, I must warn you against being too dogmatic in the course of yours. Old women must have their way, and their ways are almost always based upon prejudice; you, therefore, should be prepared and willing to consent to their notions. If you perceive a very especial desire for the application of the abdominal bandage, my advice to you is by all means to consent to it; it is only necessary for you to see that it is not put on so tight as to endanger your patient to future uterine inconvenience.—*Canada Medical Journal*.

**HÆMORRHAGE FROM THE GUMS.**—Mr. C. Wrixon says, "I have met with two cases of alarming hæmorrhage from scarification, but had no difficulty in arresting it by making pressure with a graduated compress of lint well saturated with tincture of muriate of iron."

## VARIOLA COTEMPORANEOUS WITH VACCINIA

By ROBERT FOWLER, M.D.,

Resident Medical Officer to the Loughborough Dispensary.

ON March 31st last, I vaccinated Marianne W——, aged three years, a perfectly healthy child. When next seen, April 7th, I was told that on the very day (April 1st) following vaccination she became very sick, vomiting frequently, and feverish. On the evening of the next day (April 2nd), the mother fancied that there was a little redness about the chin, which, however, on the 3rd of April, assumed the aspect of decided papulæ over the whole face, arms, legs, and body. I now ascertained that at the school to which the child had gone up to the day of its being taken ill two or three of the scholars had had the small-pox about a month ago, and had returned among the other children some few days back.

April 7th. The vaccine vesicles (seventh day) are larger than the variolous, very little elevated above the cuticle, irregular in shape, being not perfectly circular, but flattened and indented, and lobulated at the edges. There is evidently very little fluid in them, and no appearance of areola. The whole body is marked with distinct variolous vesicles (fifth day), having the same flattened aspect as, but smaller than, the vaccinia; and being so little elevated above the surface, they do not present that "shotty" feel so characteristic of variola, especially in its papular stage. Febrile action slight. 9th. The variolous eruption is more turgid; that on the face is pustular, and a few of the pustules are beginning to scab; that on the arms is hemispherical, prominent, and pustular; that on the legs is opaque, but not distinctly pustular; the central depression still existing in some of the vesicles. The vaccinia is not more elevated, though the fluid seems more opaque; the vesicles are now about half an inch in diameter, but still present that irregular, indented appearance round their margin, external to which there is now an areola of about one line in diameter, as there is also around each variolous pustule. The variolous vesicles in the immediate neighbourhood of the vaccinia are much smaller and less opaque than elsewhere, neither are they so turgid or spherical as in other parts of the body. The mother attributes this to the child always lying on that side (the right), and certainly the left arm (which, however, by some oversight was not vaccinated) presents well-filled vesicles; the eruption of the right leg also is somewhat less prominent than that on the left, though certainly there is not that marked difference observable in the vesicles of the two arms. 10th. Variolous eruption entirely pustular, scabbing going on in the face. Areola of vaccine vesicles no larger, though the vesicles themselves are larger, and beginning to lose their indented margin. The variolous eruption around vaccinia is now pustular. 12th. Scabbing progressing on the face, and the pustules on the arms shrivelling up; no secondary fever; a scab perceptible on each vaccine vesicle; no increase of areola, nor is there any surrounding induration. 14th. Some of the pustules on the legs shrivelling; vaccinia scabbing, the scabs being rather conical, and of a dirty light brown in colour; no increase of areola. 16th. All the pustules of the legs shrivelling; scabs of vaccine vesicles have fallen off, leaving an irregularly circular, purple-red mark, larger, though otherwise similar, to the stains of the variolous eruption; the vaccine stains are perfectly flat and smooth, without the slightest indication of the small depressions and radiating lines characteristic of a good vaccine cicatrix. 19th. The whole body presents purple-red stains.

**Remarks.**—Considering vaccinia as a disease *sui generis*, we have here two exanthemata coexisting in one person, and each by its presence modifying, but not superseding, the regular course of the other. That the vaccinia was modified, is shown by the irregular shape and flattened condition of the vesicles, by the absence of the areola and surrounding hardness, by the shape and colour of the scab, by the duration of the eruption—the scab having fallen off on the sixteenth instead of about the twentieth day—and

by the character of the remaining cicatrix. The size of the pustules and the absence of the secondary fever, notwithstanding the duration of the eruption, was not considerably shortened, indicate that the variola was of a modified kind. By those sceptical of the prophylaxis of vaccination, the above case will be greedily seized on; but are we not from past experience warranted in surmising, and even affirming, that, although the discovery of Jenner was in this case incapable of arresting or superseding the progress of the poison already concocting in the blood, yet that to the coexistence of the vaccine virus this child owes the safety and mildness of its attack.—*Lancet*.

#### ON FRACTURE OF THE ANTERIOR INFERIOR SPINOUS PROCESS OF THE ILIUM.

By C. W. ASHBY, M.D., of Culpepper County, Virginia.

As I have been informed by my friend Dr. Mütter that "there is no such case on record as the fracture of the anterior inferior spinous process of the ilium," I will endeavour to detail the symptoms of the accident, which occurred in my practice, in such a manner as to enable the profession to judge of the correctness of my diagnosis.

A strong athletic negro man, aged 19, was walking rapidly from a spring, and the night was very dark, he stepped into a gully about a foot and a half deep. He had upon his head at the time an unusually large tub of water. Although he did not fall, he was so disabled as to require the assistance of men to carry him to the house.

There was great loss of power in the right leg, though not entirely deprived of muscular control, except as to elevation. As I could make the limb perform all the natural movements without much pain, and as I could not perceive, after the most careful examination, the slightest distortion, no lengthening or shortening, I decided, very confidently, that there was neither fracture nor dislocation. But the patient, who was more than ordinarily intelligent, insisted most strenuously that he heard and felt something give way, not only at the time the accident occurred, but whilst I had been making the examination.

Upon elevating the leg at right angles with the body and letting it down rather suddenly, I now, for the first time, heard a crepitus, I confess much to my surprise. By this particular movement, and by no other, the crepitus was so distinct as to be heard, not only by myself, again and again, but by all the bystanders. What fracture have I here, was a most natural inquiry. From the history of the case, I was at first inclined to suspect, though in a young subject, a fracture of the neck of the bone; and being aware of the various natures, as well as great obscurity of this accident, my mind was directed most anxiously to its investigation. Reasoning by exclusion, I became satisfied that this could not be the fact; there was not a single symptom which is usually present in this accident. There was little or no pain or tumefaction about the joint, and indeed not a sufficient amount of irritation to warrant the belief that there was a fracture of any of the large bones, either of the pelvis or leg.

I requested the patient to direct my hand to the spot where he felt the greatest amount of pain. He placed it in his groin, where I detected for the first time a good deal of tenderness and tumefaction. Pressing two fingers of my left hand firmly upon this spot, and with my other hand elevating the leg and letting it down as before, I not only heard the crepitus, but I felt distinctly a spiculum of bone moving under my fingers. This manifestation, not very painful to my patient, was performed not once, but I may safely say more than twenty times, and invariably with the same result, before I decided positively as to the precise character of the fracture.

I was surprised to find that I had been poring over this case at the dead hour of night, for more than three hours. I had never heard or read of such an accident, and therefore only those of my professional brethren who know me best, can appreciate the deep anxiety I felt as to

making out a correctly satisfactory diagnosis. The maxim that "there is nothing new under the sun," often repeated by a distinguished professor of my Alma Mater, did not fail to make an impression on my mind, and, properly understood, ripper years have served only to deepen that impression. I have not the slightest shadow of a doubt as to the correctness of my diagnosis. As to its novelty, I have the high authority of Dr. Mütter, as well as that of other distinguished surgeons, and yet I am of opinion that the accident has occurred before, but either has not been recognized, or has not been thought worthy of being recorded.

Whether the process was pulled off by the powerful contraction of the recti muscles, or by the tremendous jar of the head of the bone, thrown, in the act of stepping forward, upon the outer edge of the acetabulum, or by both causes conjointly, I leave for others to decide.

The treatment of this case was as effectual as it was simple, and the result, I think, confirmed the diagnosis.

After flexing the limb, a roller, six or eight yards long, was passed firmly around the thigh, so as to control muscular action, then passed firmly over a wet compress, placed over the process, thence around the body, and back over the compress and around the thigh again. The patient was placed on his side, and experienced immediate relief, so that he slept soundly the balance of the night. Strict rest was enjoined, and he suffered little or no pain after the bandage was applied. In four weeks he was walking about, but wore the bandage and compress for several months, as it gave him great support.—*Phil. Med. Ex.*

#### ON INFANTILE PARALYSIS.

In an essay by M. Rilliet, on "Essential Paralysis of Infants," we find a large amount of interesting matter, the most practical portion of which we shall endeavour to condense:—

1. *Definition*.—The author applies the term "Essential Paralysis" to more or less complete loss of power, with or without loss of sensation, and unaccompanied by any signs of lesion of the nervous centres. This form of paralysis is often incurable, but does not of itself shorten life, for which reason it is difficult to find its structural causes; for even if the spinal marrow or brain shall exhibit certain lesions, it becomes doubtful whether they are not the results, rather than the causes, of the paralysis.

2. *Seat and Mode of Attack*.—Essential paralysis occurs in three different ways: Sometimes it attacks the patient suddenly in its highest degree, and without obvious cause; at other times it is preceded by cerebral disturbance and convulsions, as during dentition, but in these cases also the loss of power is sudden, and not progressive; thirdly, it may approach gradually. When paralysis is sudden, and not preceded by cerebral symptoms, it mostly appears in the upper extremities. An infant goes to bed well, and next morning it is found paralysed in one arm. Another sits on the damp ground, and one leg is suddenly discovered to have lost the power of motion. At the same time there is no perceptible derangement of the general health. When cerebral symptoms precede, these usually consist of somnolence, strabismus, dilatation of the pupil, and headache. These symptoms speedily subside. At other times violent and repeated convulsions occur; these cease, and paralysis is found to have supervened. Paralysis sometimes succeeds chorea, as in the cases cited by Drs. Kennedy and Lee. It also appears in the course of exanthematic fevers, and is then generally discovered for the first time when convalescence commences.

3. *Symptoms and Progress*.—In whatever way infantile paralysis commences, it presents two periods—one, that of paralysis; the other, that of atrophy. In some fortunate cases the disease does not proceed to the latter extent. The symptoms vary with the part affected. If the arm is the seat of the disease, it hangs lifeless, and if lifted falls again to the side. The paralysis is sometimes complete, at other times limited to certain sets of muscles. In some instances the

fingers are flexed upon the thumb. So also in the lower extremity the loss of power may be complete, or partial. If the child does not walk, it kicks the sound leg about, while the other lies motionless. The paralysed limb is not the seat of any pain. The colour and temperature of the skin are often normal. The sensation is generally intact. In fact, the paralysis of motion constitutes the entire malady. The progress of the disease is not always the same; it may disappear completely, and rapidly, or it may persist with or without amelioration. In the latter case, sooner or later, the second period or that of atrophy commences. This is marked by diminution of temperature, wasting of the muscles, and arrest of growth of all the structures together, so that the limb is perceptibly smaller and shorter than the other. In proportion as the temperature diminishes so does the skin change colour, becoming more and more livid. Fresh observations on the condition of the vessels of paralysed limbs are necessary, but it is obvious that these tubes are involved in the general atrophy. The pulse at the wrist is, in some cases, scarcely to be felt. As a further consequence of infantile paralysis, the spinal column becomes variously distorted, and the limbs themselves may be deformed. Thus in paralysis of the arm, and atrophy of the deltoid, the head of the humerus may be completely dislocated, the weight of the limb stretching the capsular ligament, until it allows the head of the bone to glide out of the glenoid cavity. Such cases are described by West, and one is reported by the author of the present memoir. Heine has described deformity of the lower limbs thus paralysed, consisting of flexion of the thigh upon the pelvis, and of the leg upon the thigh. The paralysis of one set of muscles, and antagonistic contraction of others, gives rise to the different varieties of club-foot.

4. *Prognosis.*—Essential paralysis does not compromise life, but as it in some cases disappears rapidly and completely, while in others it is perfectly incurable, it becomes important to determine the circumstances which should lead to a favourable or an unfavourable prognosis. This, according to Kennedy, is to be known by the manner in which the paralysis has occurred. The author of the present memoir does not agree in this opinion to the full extent, but he admits the value of the observation as approximative. Thus he thinks we may hope for a perfect cure, when the paralysis has succeeded contraction; also a complete though tardy cure may be expected when it has come on after chorea, or in the course of an attack of fever. The case is more hopeless when the paralysis is preceded by convulsion; so also when the paralysis is gradual in its approach. The result is but little influenced by the part affected. Dr. West considers the prognosis to be greatly influenced by the duration of the affection at the time treatment is commenced. Of six cases of cure reported by him, four commenced treatment within two days of the attack, while eight, in whom no treatment was adopted until the lapse of six months, remained permanently paralytic.

5. *Causes.*—Authors agree that this form of paralysis is more common in the first and second years of life than subsequently. In two-thirds of the cases on record, the child was between the ages of six months and two years. However, West, Kennedy, and Heine, have known the disease to attack children as late as five, six, and seven years of age. Sex has no influence on the disease. It is more likely to occur, in the opinion of some writers, in robust and well-formed, than in feeble and ill-nourished children, but such is not the author's experience. Among the occasional causes may be mentioned chills and blows.

6. *Diagnosis.*—The diagnosis of paralysis is not difficult, but it is not always easy to say whether the palsy is essential or symptomatic of lesion of the nervous centres, unless the symptoms of the latter diseases have been well marked. The diseases of the brain which commence in convulsions at the age of infancy, and lead to essential paralysis, are meningitis, tubercular abscess, and meningeal apoplexy. The two former diseases are generally accom-

panied by disturbances of the sensorium, which are not seen in simple paralysis, and are moreover generally mortal. The same may be said of meningeal apoplexy, which is moreover commonly followed by tonic contraction of the limb. M. Ozanam believes that meningeal apoplexy is the cause of all the cases of paralysis, which are preceded by convulsions, but he does not adduce a single fact in support of his theory. This form of paralysis can be confounded with diseases of the hip only by a very careless observer, and from the progressive muscular atrophy mentioned by M. Aran, it is distinguished by the latter being an affection peculiar to adult life.

7. *Treatment.*—West and Kennedy trust to purgatives and tonics, but allude entirely to the treatment of the stage of simple paralysis. Heine goes deeper into the subject, and endeavours to remedy the stage of atrophy also. The indications of treatment proposed by him are:—

1. To awaken the nervous power of the spinal marrow and nerves of the affected limb.
2. To restore the deformities by orthopedic measures.
3. To invigorate the constitution. For the fulfilment of the first indication he gives nux vomica internally, and applies it in frictions along the spine. Electricity has failed entirely, but he has been more successful by well regulated gymnastic movements of the wasted limb. For this purpose various ingenious instruments have been devised which our space will not allow us to particularise.—*Arch. Gen. and Prov. Jour.*

#### CASE OF SCLEREMA—OR INDURATION OF THE SUBCUTANEOUS CELLULAR TISSUE.

By NORMAN BETHUNE, M.D., of Toronto.

C. A—, æt. 17, in her first pregnancy, was taken with labour pains at eight p.m., December 28, 1851. She stated that she had arrived at the full time, but noticed it as remarkable that she had never complained, as women are wont to do in her condition, and that she had experienced no sickness at stomach till three days before she was taken in labour. The mammary glands were large, but flaccid, and presented the areola of the full period of utero-gestation. The abdominal tumour was so small, that a stranger might not thereby have suspected her pregnancy. She had once or twice experienced falls upon the ice in the course of the present winter. She was delivered of a female child twenty-two hours from the accession of pains, nothing remarkable having in the meantime occurred. The child struck me as being the smallest I had ever seen at the full period. Its weight was barely over three pounds, and its length from crown to heel about fifteen inches. (The average weight at this period is seven pounds, and the length twenty inches). In other respects the child was perfectly developed, the condition of the nails and hair, and the position of the umbilicus, being such as to indicate the complete term of uterine life.

The limbs were well clothed with muscle, but rendered almost wholly immoveable from the extreme tightness of the skin, which was hard, resisting, and of a morbidly red colour. This condition of the integument was pretty general throughout the body, but was much less marked about the face. It was particularly tense in the region of the pubes and perineum, producing an evolution of the mucous membranes of the vagina and rectum. The oral aperture at times assumed an orbicular shape, while the surrounding skin took on a purplish or dusky hue. The temperature of the surface was much diminished. There was no appearance of œdema.

As soon as respiration was sufficiently established, it was wrapped in warm flannel, and afterwards well washed and bathed in warm water, soon after which it cried out lustily; but this cry gradually fell away to a moan, which continued till its death, which happened five hours after birth, the tension of the skin having become more general, and having increased to such an intensity as to induce a change in its colour. This colour, which was a dark purple, was first noticed in the hands and feet, and thence pervaded the entire body. Death was ushered in by a general tetanic spasm.

We have here an example of what may be termed the acute form of that fatal but fortunately very rare affection known as the skin-bound disease, the oedematic concrete, or sclerema of French authors. It is not distinctly mentioned till 1716, when Usemborzius published a case of it. Since that time we have had good descriptions of it by Dr. Underwood and M. Andrij, as it appeared with some variations in the London and Parisian hospitals respectively. It occurs rarely, and then only as an endemic, in England, and it is not so liable to complication with tetanic spasm and erysipelas, as it is in France. Dr. Denman collates the following symptoms as pathognomonic of (the chronic form) the disease:—1st. The skin is always of a yellowish white colour, giving the idea of soft wax. 2nd. The feel of the skin is hard and resisting, but not oedematous. 3rd. The cellular membrane is fixed in such a manner that the skin will not slide over the subjacent muscles; not even on the back of the hands, where it is usually very loose and pliable. 4th. The stricture often extends over the whole body, but the skin is particularly rigid in the parts of the face, and on the extremities. 5th. The child is always cold. 6th. The infant makes a peculiar kind of moaning noise, which is often very feeble, and never cries like other children. 7th. Whatever number of days such children may survive, they always have the appearance of being dying.

In two respects the case before us presented variations; the skin was of a deep red colour from the first, and the stricture more rigid about the body and extremities. In speaking of the induration of the subcutaneous cellular tissue of early infancy, Dr. Davis remarks that the disease usually comes on just after birth: it is sometimes delayed for two or three days, while in some very rare instances (as in the present) the disease has been present at birth. He notices that the subjects of its attack are always weak and puny, and have a peculiar complaining sort of cry, not a little pathognomonic of their condition. As the disease gains ground, the respiration gradually grows more feeble, the face assumes a purplish hue, all the symptoms of suffocation arise, and death takes place by asphyxia. The body retains all the peculiar external appearances which characterise the disease during life. Having unfortunately been deprived of the opportunity of making an examination of the body post-mortem, I am unable to speak of the appearances. I may, however, allude to a few characters noticed by Dr. Davis in his dissections. The cellular tissue, instead of being compact (or indurated) was filled with a serous or albuminous fluid, either limpid or tinged with blood, the tissue remaining soft and flaccid as the fluid oozed out, and the skin which before was hard and tense now rolling under the finger. There was venous congestion every where to be seen; the lungs, liver, and all the soft parts, apparently gorged with blood. M. Andrij constantly met with a deep yellow serous extravasation, fluid, but capable of coagulation by heat; the fat peculiarly solid, the glands and lymphatics, especially those of the mesentery stuffed, and the liver uncommonly large, with a great quantity of deep-coloured bile in the gall bladder; the lungs loaded with blood, and containing an unusual quantity of air.

The cause of the disease has not been properly accounted for. The affection, as before stated, is usually endemic, arising probably from foul air, as it chiefly attacks the poor, and is generally met with in large crowded hospitals. Little can be said with respect to treatment. A remedy may succeed on one occasion and fail on another. Among those which appear to have been most beneficial are the warm and vapour baths, dry friction with warm flannels, blisters to the extremities, and at all times a strict attention to the state of the bowels from the onset of the disease.—*Upper Canada Journal*.

**SRCOSIS.**—Mr. E. Wilson says amongst the most useful applications are the citrine ointment, the iodide of sulphur, and the tar ointment. At the same time give Fowler's solution.

## ON CHORDEE.

By JOHN L. MILTON, Esq.

THERE are two facts to be noticed as to the cause of chordee as bearing upon the treatment—viz., that there is spasm, and that this is attended by pain, caused, primarily or secondarily, by the condition of the mucous membrane. The following appear the best known and most commonly employed methods of treatment:—

Mr. Lagneau says—"For the inflamed chordee, bleeding from the arm, hot bathing to the perineum, lavements, eighteen or twenty leeches to the canal of the urethra, two or three times repeated, and, when the pain is severe, gr. i. of the watery extract of opium, and gr. ii. of camphor, which he recommends giving in the evening. He winds up this energetic treatment by a solemn warning not to plunge the penis into cold water, as it may be, and has been, followed by a metastasis of the complaint of the bladder.

M. Ricord recommends gr. iiss. of camphor, and gr. ss. of opium in a pill, of which two or three may be taken every night.

Richter recommends that the patient sleep on a hair mattress, and very cool, or else on a canopy, and do not turn on his back.

Eisenmann, that the parts should be exposed to the influence of narcotic vapours; or that infusion of chamomile or cherry-laurel water be injected or dropped into the urethra. He found sedatives of no avail. He recommends the patient to make water more frequently than necessary, because a distended bladder irritates the vesiculæ seminales and the neighbouring parts. He objects, also, to dipping the penis in cold water, and then recommends soothing injections or poultices; opium being less useful.

Peyrihe recommended ammonia and injections of soap ley.

Iodine, the empyreumatic oil of tartar, and blue ointment, have also been praised.

Mr. Hunter says he has "known twenty drops of the tinctura thebaica take it (painful erection) away for a whole night, and that the cicuta has likewise some powers in this way." For the chordee, he recommends opium joined with camphor, praises local bleeding, with the free use of hot vapour to the parts; poultices with camphor; while the effused lymph which remains may be removed by mercurial ointment in friction. He has seen the cicuta of service.

Mr. Wallace recommends calomel and hippo (pulv. ipecac. comp.), with opium and camphor.

Such are the general outlines of the practice pursued by surgeons, as we find it recorded in books. These plans bear a pretty strong resemblance to each other, and are nearly all calculated to lead to one point—the allaying of pain by the use of sedatives. The idea of attempting to remove it by the pure antispasmodics, does not seem to have been worked out or even entertained, although everything seems to show that it is more amenable to them than to opium.

I now approach that part of the matter which has most of all occupied my attention—the substitution of some simple and always applicable remedy for these different methods of cure. I will not stop to point out the inutility or inapplicability of antiphlogistic treatment to this symptom, as any one versed in the disease must have observed cases where the chordee came on though the patient had been treated most heroically. Sedatives I utterly object to, as I have never used them in sufficient quantity to have any material effect on the chordee without finding the patient much worse afterwards. They generally disordered the stomach, produced headache and languor, very often with constipation of the bowels. The scalding and discharges were rendered worse and more obstinate, and, to crown all, the chordee was merely abated for an instant, and returned the moment they were left off; nay, even when they were again administered, without increasing the dose. Nor have I ever been able to understand why they should be given, as the pain appears to depend on a spasm, and when this is removed the pain ceases; whereas, the spasm does not necessarily subside when the pain is relieved.

I have tried the most powerful antispasmodics, as ether, galbanum, assafœtida, and chloroform, and can only say of them that I have found nothing equal to camphor in the fluid form. In powder, camphor is disagreeable to take, and did not appear to act so readily; I suppose from not being so equally diffused and finely divided as in solution. In fact, in spasm a liquid remedy, as admitting of a more rapid action, is always the thing to be sought for. The spirit of camphor, taken in the dose of ʒi., in a small quantity of water, is

equally energetic and rapid. The objection that it immediately becomes insoluble by contact with water, is sufficiently obviated by the fact, that its operation is most certain and rapid, and that essence of camphor, in which the camphor is so dissolved that it does not separate on the admixture of water, possesses, so far as I have been able to judge, no advantage over the other.

As in many other cases, the chain of morbid actions must at once be broken; and this is done much more effectually by two or three full doses, repeated at short intervals, without the least remission, till the chordee is completely stopped, than by small quantities, however long continued and regularly taken. I therefore invariably adopt the following plan.

A teaspoonful is to be taken at night in water before going to bed, and every time the patient wakes with the chordee, *let him at once rise and repeat the dose*. In the milder cases, one dose for a night or two is generally enough; in the more severe ones, the symptom is generally removed at the end of the second night, becoming, in the meantime, milder and less frequent after each dose. So long as the clap remains bad, I frequently recommend the patient to take a teaspoonful at night, before going to bed, which suspends the chordee till the cure is completed. This plan of treatment also answers well in the bearing-down pains to which women are sometimes subject in clap; but as here, contrary to what it is in men, these pains are generally worse in the day time, it is best to use the essence of camphor largely in the medicine they may happen to be taking.

It must, however, be taken in full doses. A violent sudden pain, like that of chordee, requires an equally powerful remedy, and there is no use in trifling with it. A less quantity than a teaspoonful will not always suffice to abate the pain at once, though it may materially alleviate it; just as a moderate dose of chloroform will lull the acute pain of an operation without rendering the patient insensible to what is going on, while a smaller quantity, in one full dose, produces complete torpor. Now, as a teaspoonful or two may be safely taken, it is better to ensure success at once. In one or two cases it has produced some sickness, and, strangely enough, this has been more the case with small doses than large ones. This was probably caused by something having been previously taken that had in some measure disordered the stomach. At any rate, the instances have been too few to make the affair of any moment. I only allude to it here that no one might by its appearance be discouraged from giving so valuable a remedy as camphor really is.

The patient should be directed to keep the camphor in a tightly corked bottle, and in a cool place, and to have it by his bedside ready to take. It is best taken in water, as if dropt on sugar it produces a strong sensation of heat in the mouth, occasionally preventing the patient from getting to sleep again.—*Medical Times*.

#### EFFECTS OF IODINE ON THE MAMMÆ.

By Mr. BRYAN of Northampton.

ELIZABETH MARLOW, aged 16, of robust healthy appearance, had menstruated regularly for more than twelve months, was very fat generally all over the body, and with very large mammæ for her age, applied to me, January 12, 1836, for relief of bronchocele, there being great enlargement of the thyroid gland, both in front and at the sides, causing considerable uneasiness from pressure upon the adjacent parts. She commenced using unguentum hydriodatis potassæ, rubbed into the swelling for fifteen minutes every night, taking inwardly at the same time five drops of the compound tincture of iodine three times a day, which treatment she persevered in until March 14, when she commenced applying the tincture to the swelling, night and morning, instead of the ointment. This treatment was continued until April 23rd, when she began to suffer from giddiness and defective vision, and left off the iodine both internally and externally, as it was evidently affecting her health, the flesh losing its firm feeling and appearance, and she was becoming altogether out of health, and was placed under other treatment, having reference to her particular condition, in June and July, consisting of effervescent saline medicine, with alterative aperients. Nevertheless, she gradually became thinner, so that towards the end of the year the mammæ were quite wasted away, and there was a general wasting of the whole body, tending to the supposition that she was in a rapid decline. The bronchocele had also wasted very considerably, although not so much in proportion as other parts. In the beginning of 1837, under a restorative plan of treatment, she gradually

altered for the better, and became again in a few months quite *embonpoint*, and so she has remained until the present time. The bronchocele enlarged also, and is now much the same as at the commencement of the treatment.—*Prov. Jour.*

Have the mammæ been restored?

#### PROGRESS OF THE PHARMACY BILL.

IN consequence of the delay occasioned by the Easter recess, the Select Committee on the Pharmacy Bill has not concluded its labours. Five sittings have been held, during which evidence has been received from physicians, surgeons, and general practitioners connected with the several colleges and corporations in London and Edinburgh, and from representatives of the Pharmaceutical Society. Evidence has also been taken on the laws relating to pharmacy in France, Germany, Sweden, Finland, the Mauritius, &c.

The comparison thus instituted is by no means favourable to the character and credit of our own country. The pharmacists or apothecaries on the continent of Europe (who represent the class of chemists and druggists in England) are obliged by law to pass through a regular education extended over several years, and comprising all the subjects required for the due performance of their functions, and the practical application of this knowledge in a shop. The examinations (in some countries three in number) are searching, and occupy several days. This education and the examinations are conducted in institutions under the direct control of the government. No person can practise pharmacy without possessing a diploma or licence, obtainable only after examination. In some instances the number of shops is limited, and no new shop can be opened except by licence from the government. The prices of medicines are fixed by the authorities, according to a tariff, a discount being allowed to the poor. The shops are visited at intervals, bad medicines thrown away, and unless the regulations which the law requires are found to have been complied with, the offender is liable to punishment. The sale of poisons is placed under strict rules. They can only be sold by the authority of a medical practitioner or a government inspector, and must be kept in a distinct part of the shop. A general disposition prevails to separate pharmacy from medical practice. In some countries this is strictly enforced; medical men are prohibited under a penalty from selling medicines, and pharmacists from practising as medical men. There are some exceptional cases: for example, in villages where the division of labour could not be carried out, medical men may sell medicines on obtaining a licence from the government authorities, and in cases of emergency, or the necessities of the poor, pharmacists occasionally administer remedies according to their judgment. But this is done to so limited an extent, that it does not amount to an abuse, and does not appear to occasion jealousy in the medical profession. In some of the details, the laws vary in different countries, but the above is a very brief general outline of the regulations on the continent of Europe and in the Mauritius, which originally derived its laws from France. From the attention which is paid to scientific education, it results that many eminent men rise from the rank of pharmaceutical chemists in these countries, profiting by the early tuition which forms the groundwork of their acquirements, they proceed in the several branches of science which are suited to their taste and ability, until they have obtained a celebrity creditable alike to themselves and to their country.

Turning from this glance at foreign pharmacy to the condition of that branch of the profession in Great Britain, the contrast is humiliating. We have some clever practical men of business fully competent for their duties as dispensers of medicine, we have some self-taught chemists engaged as manufacturers, either separately or in conjunction with the dispensing business, and we have an indefinite number of pretenders to the rank of Pharmaceutical Chemists, possessing no education whatever, arrogating to themselves the insignia and titles of qualified men, frustrating the intentions of medical practitioners, and endan-

gering the lives of her Majesty's subjects. Whatever qualification is possessed by any of these parties is more than the law requires—as the law requires nothing.

It is needless to recapitulate the disadvantages resulting from this defective state of the law, as these have been frequently adverted to in this journal. The facts of the case are now before the Select Committee, with the bill which has been prepared as a remedy for the evil, after many years of consideration and experience.

The laws on the continent to which we have referred contain some severe restrictions, and a system of centralization and monopoly, which would not suit the habits and prejudices of Englishmen. These provisions are avoided in the Pharmacy Bill, which contains only those elements of improvement which are calculated to produce the desired effect without interference with our national and constitutional peculiarities. Some objections, however, have been urged against the bill under the impression that it would interfere with the privileges of certain medical bodies, and on other grounds which we have already pointed out, and amendments have been proposed to meet them.

The notions which we have heard in some quarters respecting the supposed monopoly created by the bill are worthy of remark. The bill creates no monopoly so far as the medical profession is concerned, as its operation does not extend to prejudice or affect the several licensing bodies comprised in the profession, or their licentiates. Nor does it establish a monopoly on the other side by prohibiting the sale of drugs by small shopkeepers, not regular druggists. But it simply recognizes the class for whose education it provides, as a body qualified to assume the name and carry on the business of Pharmaceutical Chemists. The monopoly, if there be one, is in the assumption of a name or emblem implying qualification. The public may purchase medicines where they please; but if they go to a person who is not qualified, they are not to be deceived by the display of that which is usually taken as evidence of qualification, they employ a person not recognized as a chemist with their eyes open and at their own peril. This distinction between the regular and irregular vendor of medicines will serve as an inducement to all those who embark in business as *bona fide* chemists and druggists to pass through the ordeal which the safety of the public requires in order to place themselves on the rank of recognized chemists. It will thus raise the qualifications of that body, without fettering the sale of common medicines in small villages by the jack-of-all-trades, who deals in everything. But it is objected that the exclusion of medical men from the register of chemists and druggists is an act of monopoly. This exclusion is intended as one mode among others of promoting the separation of the two bodies, ensuring the continuance of the Pharmaceutical Society as a strictly pharmaceutical body, and thus avoiding the example of the Society of Apothecaries, which has become a medical body. Medical men can perform all the functions of chemists and druggists in their own capacity, as medical men whose education includes pharmacy. They can assume the name of chemist, &c., the prohibition against this assumption having been removed from the original bill in compliance with the wishes of parties who raised an objection to it. Having retained the power of practising pharmacy and of assuming the name, some are still not satisfied because they are not to be included in the register. What they would gain by such inclusion it is difficult to understand. They claim to be considered a superior body, yet they are aggrieved at not being included on the register with those whom they view as inferiors.

Again, how can this desire to amalgamate themselves with the pharmaceutical body be reconciled with the apprehension lest that body should become medical? What could tend more to promote the assumption of a medical character than the inclusion of medical men into the ranks? They are excluded in order to maintain the separation, and secure the purely pharmaceutical character of the Society. Yet it is alleged, on the other hand, that the

bill is an invasion of the province of the medical profession, and that the elevation in the character of chemists will cause them to become medical practitioners. It has been repeatedly stated in the most positive terms that the intention and tendency of the bill are exactly the reverse, that medical men are even excluded from the pharmaceutical body, and that it is one of the objects of the bill to create a separation so far as may be found practicable between pharmacy and medical practice in a manner satisfactory to all parties. We cannot understand on what principle the improved education of chemists, as *chemists*, can be objected to on the ground that this is an invasion of the medical profession. Several medical practitioners who object on this ground have been requested to attend the committee and explain in what manner this evil is likely to result from the bill, and how the evil may be averted.

The questions at issue being under the consideration of the Select Committee, we trust that a mutually satisfactory arrangement will be effected. We are not at present in a position to predicate what may be the decision of the committee on these questions; but the bill, in its amended form, will be reprinted, and the opportunity will be afforded for the reconsideration of the entire measure. We do not at present anticipate any serious alterations in the bill, as nearly all the objections we have heard are founded on a misapprehension as to its objects and intended operation.—*Pharmaceutical Journal*.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MAY 19, 1852.

### PROSPECTS OF MEDICAL LITERATURE.

WE learn from a speech delivered by Mr. GLADSTONE in the House of Commons on Wednesday last, as well as from sundry revelations (epistolary, post-prandial, and plat-form) which have lately flowed through the "usual channels," that there is a "rustling under the straw," portending no small advantage to the medical profession. It seems that publishers and booksellers have fallen into what, on the other side of the Atlantic, is called "a difficulty;" and in settling it, there is a chance that authors in general may come in for a fairer share of the loaves and fishes than heretofore, and possibly medical authors amongst the rest. In fact, the old adage may be expressed by a version to the effect, that when "the trade" fall out, "the doctors" may come by their own. Here, however, is Mr. GLADSTONE's account of the state of the question:—

It is probably within the knowledge of many whom I am addressing that a most interesting, and, I think, a most important struggle, is now in progress in the book-trade (hear); that, as I think most unfortunately, a large number of the booksellers of London and of the country—some say using the publishers of books as their instruments, others say led on and authorised by the publishers—are attempting by restrictions, as it seems to me, of a most imprudent and unwarrantable character, to prevent the price of books, which is so enormously high, from being mitigated even to the extent of a few shillings per cent. by the enterprise and energy of those among the retail traders who are disposed to give the public the advantage of that enterprise and energy (hear). I think it would be very unjust at the present moment to bear hard upon this body of publishers and booksellers, because, in a spirit which I think does them honour, they have consented to refer the question to the judgment of some distinguished persons (hear); and at this moment Lord Campbell, with Mr. Grote and the Dean of St. Paul's, is engaged in the consideration of this question: and they have, I believe, kindly undertaken to give their judgment upon it (hear). To that judgment, I believe, the London traders in books are prepared to submit (hear). I must confess I cannot much doubt what it will be (hear). The house should be aware what is the exact nature of the question. The publishers of

books are in the habit of supplying the retail traders at a fixed price, that price being usually (with the exception of the case of wholesale purchases) at a discount of 25 per cent. upon the publishing price. The custom of the retail trade is, not to grant the public who purchase a greater discount than 10 per cent., leaving 15 for the retail trade (hear). Some retail traders say they can give a greater discount than 10 per cent.; but then this combination steps in and says, "You shall give no greater discount than 10 per cent. to the public, and if you do not come under an engagement to that effect, we by combining among ourselves will exclude you from the trade in books;" that is, deprive you of the means of livelihood in the vocation to which you have devoted yourself. This restriction is in my view a great evil (hear). I do not pretend to compare the price of new publications with that of articles of bodily subsistence in regard to the urgency of the questions they raise; but I do say, that it is a very great evil that the price of books should be raised above what may be called the natural and legitimate amount (hear). And further, I venture to say, that the state of the book-market, except so far as it is partially mitigated by what are called cheap publications, is a disgrace to the present state of civilization (hear). The controversy now going on with certain retail traders who in my opinion deserve great credit for the energy with which they have struggled against the power they have endeavoured to cope with, is but a part of a system (hear). I wish the house were aware of the facts in regard to the production and the sale of books in this country. The truth is, that monopoly and combination have been so long applied to the whole subject, that they really have gone near,—I do not say to the extinction of the trade, but to reducing it to its minimum (hear). We have a country that has by far the largest educated class in the world. (A Member.—"There is America.") I was thinking of Europe, but even taking America into account, we have a country in which the class that ought to be purchasers of new books is the largest in the world; I mean the educated class in that sense—the men in possession of such fortune as ought to make them the natural purchasers of new publications. That class in this country is counted by twenties, and by fifties, I might almost say by hundreds of thousands. But what is the fact with regard to the state of the book-market? It is, that with the exception of certain very highly-esteemed and distinguished authors—with the exception of such cases as Mr. Macaulay's History of England,—what are called new publications, not only in a majority of cases, but in an enormous majority, scarcely ever pass a sale of 500 copies. An immense proportion of those that are published do not pay their expenses at all; and I believe the proportion of them passing the sale of 500 copies in this country, with its enormous means for the cheap production of books, and for supplying an extensive demand for them, is not more than something like 5 per cent.; or, at any rate, not more than from 1-20th to 1-10th of the whole number produced (hear). Now what is the consequence? It is a matter within our personal experience. The purchase of new publications is scarcely attempted by anybody individually (hear). You go into the houses of your friends, and, unless in the case of books for which they have a professional want that must be satisfied, or unless they happen to be persons of extraordinary wealth, you do not find copies of new publications upon their tables, purchased for themselves; but you find something from the circulating library, or something from the book club. Let the house observe too how, in cases of this kind, one system of combination generates and maintains another. It has been the practice of the book-trade to combine (I do not use the term offensively) against the public; and what is the consequence? The printers combine against the book-trade and very naturally (hear). Ask a publisher why the price of books is so high; he will tell you one reason is, "the printers have entered into a combination against us" (hear); and is it not perfectly natural, that if the journeyman printer sees the publishers and booksellers combine against the public, he will say, "I will step in and get a share of the fruits?" and so it is. Now I hope, whenever the Chancellor of the Exchequer may be in a condition to propose to the house a remission of the paper duty, these matters will be well looked into (hear), and that we shall take care that the public revenue is not given away for the purpose of facilitating or promoting the extension of these combinations.

If such be the state of affairs as regards books in general, we can answer for it that it is ten times worse as

regards medical books. The trade in them has, Mr. GLADSTONE says of other books, been not only reduced to its minimum, but has become nearly extinct. There is, we believe, a limited sale for books required by students, the property of publishers, but for works addressed to practitioners there is in many cases absolutely none. We suspect that many of our medical authors on settlement of their accounts with printers, publishers, and booksellers, find the balance at the wrong side; and that most of them are well satisfied to escape without loss. Some of them will deny this, and talk of the success of their literary labours; but we cannot believe them until we see both sides of the account, for we know that the writings of many of our most distinguished men have obtained no pecuniary reward. We ourselves heard Mr. ABERNETHY say that he never received any money for his publications; and so it has been with others of equal celebrity. Much of this is doubtless owing to the monopoly and combination in the trade, now under discussion, but much of it is owing to medical authors themselves. Of the sale of many publications no hope is entertained, because they are printed merely as advertisements; but of others, a fair return is expected, although seldom realized. This is principally owing to the high price demanded for them, considering their intrinsic value. Matter which might be compressed within the compass of a pamphlet of three sheets, is often expanded into a book of twenty; and to add to its consequence and effect, the most expensive type and paper are employed. The inexperience of medical authors in all matters pertaining to publication, is another cause of this failure. The simplicity with which they entrust their books for publication to persons who not only can have no interest in promoting their sale, but are actually interested in their suppression, is amazing; and the trouble they take to restrict their publicity by restraints on advertising is amusing. How often have we had to congratulate ourselves on the foolish hostility displayed by medical "authors" towards ourselves, in denying us copies of their valuable productions for review or notice, while we laughed at the spirit which impelled them to sacrifice the sale of their books to the gratification of their spleen. When men allow such influence to operate in a matter of business, how can they complain if success does not follow. But there is another cause to which the limited sale of medical books is to be ascribed: many men cannot afford to pay for them, many more who can afford it, have no inclination to do so, and many more if they had them would not or could not read them. In fact, there is nothing very wonderful in this stagnation in the book-trade, nothing very surprising that the thin journal has displaced the thick volume.

#### THE DISPENSARIES.

Our correspondents save us the trouble of treating this matter in detail this day. In the letter of a "Dispensary Practitioner," the necessity for union and organization is well urged; and the sooner the suggestions offered in favour of local associations are well considered, the better. The truth is, that the new measure will require this very method for its adjustment; for it is obvious that no power exists so capable of bringing it into harmonious operation as that which the Medical Officers can wield. If the matter be taken up in a liberal and candid spirit by them, and with a determination to deal impartially with all interests, much now complained of might be rendered, at

least, more tolerable. Let useful, practical suggestions be made, obvious improvements pointed out, and crying grievances temperately exposed. As to the recovery of the arrears due to Dispensary Surgeons for services performed between the commencement of the Poor-law system and the expiration of that of the Grand Juries, we have only to say that it must be accomplished by proper legal proceedings, as we have already suggested.

## CORRESPONDENCE.

## MEDICAL CHARITIES BILL.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Have the fond anticipations for the benefit of the sick poor and the honour of the medical profession been realized since the bill of Sir W. Somerville became law, now over seven months? Alas! I fear not. I was one of those who took no part in forwarding this measure, because I could not see my way clearly in so doing, nor be satisfied that it would be an improvement on the old state of things, notwithstanding all the abuses and insults to which the profession was subject under the latter. I occasionally hear it said by some, that the bill will yet work well, and that the medical men only need patience to ensure this. I pray they may be right. But what evidence have we that justice will be had from the boards of guardians, either for the sick poor or the medical profession? All experience, particularly that of late, compels us to regard them as the “natural enemies” of both one and the other. I am aware that strong hopes were (and no doubt are) entertained that the high character of the Medical Commissioner will produce amongst his brother commissioners a sufficiency of influence to procure for the dispensary practitioners a reasonable share of justice and protection from the insults of the guardians. I trust these hopes will not be blasted. I do not believe they will. To make assurance, however, doubly sure, the medical men should *organize and work*. Were they unanimously to fight their own battles, they would defeat all attempts made to degrade and insult them. The remedy is within their own hands, for “Heaven helps those who help themselves.” Of this we had a striking instance not long since in the exertions made by the medical men of Cork, who *obliged* the Marquis of Anglesea to cancel an appointment he made to a medical situation in the person of an unqualified man. The south of Ireland furnishes another instance where organization was marked by signal success. I allude to the last outbreak of cholera in the country. I read with much pleasure the accounts given of the successful manner in which the faculty of Cork wrested from the public authorities a *reasonable* remuneration for their arduous labours in treating that formidable disease, and am assured that this never would have been accomplished except by unanimity and determination.

Our present position is important and critical. How blind are we to our own interest and respectability if we do not exert ourselves at such a time. In the MEDICAL PRESS of May 5, is an excellent letter, signed “One of the Dispensary Medical Officers,” which has met general—almost uniform—approbation in this neighbourhood. The writer clearly exposes the absurd idea, “that any great number of the profession would, or could, assemble in Dublin, except on some rare and extraordinary occasion.” In place of this, he shrewdly suggests what you, sir, wisely advised—viz., “the organization of local associations” throughout the country. His suggestions appear so practical, that I will quote what he says on the matter:—“The profession, then, can be effectually organized only by the creation of county associations; and it so happens, that a staff is already in existence that can easily promote their development. The estimable Chairman and Secretary of the Committee of Medical Attendants, &c., have but to issue a brief circular to their local secretaries throughout the country, to call a meeting of the profession in each county for this purpose, and the thing is done. Of course, each county association should have a chairman, secretary, and other officers. These, in each province, would form a provincial committee; and on important occasions they could assemble in Dublin as a national committee. In this way, full attendance and representation at the provincial and national meetings would be ensured; for each of these officers would feel himself bound, in his official capacity, to attend; and even in the intervals of these meetings, the county associations, by corresponding with each

other, could act in unison and with a weight that would compel respect.”

Fully agreeing with these views, and sincerely anxious for their speedy accomplishment, I have the honour to remain your obedient servant,

A DISPENSARY PRACTITIONER.

May 13, 1852.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Is it apathy, or are the members of the profession so enraptured with the brilliant prospects opened to them by the working of the Medical Charities Bill, that they sit so quietly down under the monstrous wrong done them, in leaving them without remuneration for the onerous and expensive services rendered by them to the sick poor in their respective localities during the period that has elapsed since the act became law? If the medical officers of the late dispensaries are but true to themselves, there are those possessing rank and influence who are ready, aye and able too, to render their assistance. Let them for once unite as a body, and forward a temperate and plain statement of their case to the government, and I have reason to know that their application for redress will be attended with success. If the machinery of the old Medical Association cannot be brought to act, why not look to that old and well-tried friend of the body—Dr. Kingsley of Roscrea? He, I am sure, will be found now as hitherto ready to take the initiation in the matter. *Verbum sapientie*.—Faithfully yours,

A DISPENSARY SURGEON.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—As you desire to be kept informed of the working of the Dispensary Act, I write to acquaint you with an order of the board of this union, whereby the Board of Guardians plainly shows its desire to usurp the functions of the Poor-law Commissioners, Inspectors, and Dispensary Committee, by requiring of us information only obtainable by our keeping another book, in addition to the already tolerably extensive library with which we have been supplied, and information evidently intended to enable them to torture us unfortunate doctors by their incessant and intolerable interference with the inspectors and committees in the discharge of their proper duties as “managers” of the dispensaries. The following is the order:—“Ordered (in pursuance of section 11 of article 17 of the Commissioners’ Regulations prescribing the duties of the Medical Officers of Dispensary Districts) that the several medical officers of the dispensary districts be requested to furnish the clerk, for the information of the board, on or before each board day, with returns, stating under the head of each day of the week ending on the previous Saturday—1st, their attendance at the several dispensaries, with the time of such attendance; 2ndly, their attendance on patients at their houses, stating names and residency of such patients.”

They then suggest a form, and kindly promise to print it, if approved of, after a few weeks trial. To this I mean to reply, “that the information required is not obtainable from the dispensary books,” saying no more. You might suppose that ours is a very exemplary board and most zealous in discharge of its duties. You will be surprised then to hear that, up to this day, no place has been prepared for the dispensary of this town with its 10,000 inhabitants, and that I am actually obliged to send away from the old house (which we are suffered by the owner to use in the interim) numbers of legitimate applicants for relief from the want of medicine, which should have been supplied to us by the board several weeks ago. Perhaps you would be kind enough to advise as to the wisest mode of resisting this encroachment.—I remain your obedient servant,

A MEDICAL OFFICER.

## HOMŒOPATHY.—£500 REWARD!

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—You in your simplicity would advise aspirants to medical fame to drink deeply at the fountains of knowledge, to acquire the power of medical thinking, and to practise the healing art conscientiously on all men. In real life a man should invest his capital in a “snug practice and a handsome retail” attached thereto, the business of the establishment being carried by old rules with a view to gain; or he should learn a system rejecting rules and despising all knowledge, truth, and experience, conscience being seared as with a hot iron.

The system of homœopathy is based on an untruth, and supported by knavery, ignorance, and misquotations from foreign writers. It is practised by the uneducated in medi-

cine, who are guided by cunningly arranged books, and by men who may know more of the truth than it would be lucrative for them to acknowledge.

Your many able articles, exposing the unprincipled nature of homœopathy, have excited much table-talk, and caused disclosures of the malpractices of our avaricious brethren, who have been at various times heads in allopathic practice, yet still many good, unsuspecting, ignorant people are gulled and thrall'd by this deception.

I would therefore beg you will direct the attention of your readers to the *Herald* and *Warder* newspapers of this city, where, during the past week, the sum of £500, in separate hundreds, are offered for proofs that the homœopathic "immutable law" is true. It is hoped that the love of money may tempt some of the leaders into the field, and that discussion may open the eyes of their dupes. I know that you seldom descend to consider etiquette or the doings in private medical practice; that you confine yourself to the doings and sayings of the schools, colleges, their great men, and to the legal starvation of the newly-fledged public doctors; yet I hope you will ere long deem private practice worthy of your notice.—Yours,

A SUBSCRIBER.

May 6, 1852.

#### UNIVERSITY OF ST. ANDREW'S.

LIST of gentlemen who had the degree of Doctor of Medicine conferred upon them, 7th of May, 1852:—Francis Ayrton, M.R.C.S. and L.A.C., Liverpool; William Burns Beatson, M.R.C.S. and L.A.C., Peckham, Surrey, H.E.I.C.S., Bengal; James Strange Biggs, M.R.C.S. and L.A.C., Devizes, Wilts; Charles Blatherwick, M.R.C.S., Tichfield, Hampshire, E.; James Boyd, Lic. Fac. Phy. and Surg., Glasgow, Beith, Ayrshire; Richard Cross, M.R.C.S. and L.A.C., Scarborough; Robert Butterfield Cumming, M.R.C.S., London; James Drummond, M.R.C.S. Ed., Edinburgh; David Duncan, M.R.C.S. Ed., Glasgow; Edward O'Callaghan Foott, M.R.C.S., Cork, Ireland; Benjamin Godfrey, L.A.C., Romsey, Hampshire; Edmund Grosvenor Goulden, M.R.C.S. and L.A.C., Hazel Grove, Cheshire; John Grabham, F.R.C.S. and L.A.C., Essex; Horace Edward Philogonius Johnson, L.A.C., London; William Locke, M.R.C.S. and L.A.C., Hoddesdon, Herts; Charles Martin, M.R.C.S. Ed., Leicester; Samuel Mault, M.R.C.S. Ed., Nagercoil, S. Travancore, East Indies; James McCann, M.R.C.S. and L.A.C., London; Richard Budd Painter, M.R.C.S. and L.A.C., London; George Newport Pickstock, M.R.C.S., Belize, Honduras, West Indies; John James Ridge, M.R.C.S. and L.A.C., Gravesend, Kent; Francis Salter, M.R.C.S. and L.A.C., Hayes, Middlesex; Samuel Stacy Skipton, London; Thomas James Vallance, M.R.C.S. and L.A.C., Stratford House, Essex; Watkin Sandom Whylock, M.R.C.S., Southwark; William White Williams, M.R.C.P.L. and M.R.C.S., Gloucester; John Wills, M.R.C.S., Wiltshire. Mr. Benjamin Thomas Moore passed the requisite examination, but in consequence of an informality in his certificate, his degree was temporarily deferred.

#### EFFECTS OF EASTERLY WINDS.

It has often been a subject of inquiry among invalids and their attendants, why an easterly wind should affect their health so much more than breezes from any other quarter, without reference to the actual locality in which they may be placed; and the uninterrupted suffering under which I have been labouring for the last ten weeks (solely, as far as I can discover, from the effects of the east wind), has made me desirous of information on the subject. Some local peculiarity is generally assigned as the actual cause of its deleterious effects. Thus, in town, I am told "the east wind blows over the Greenwich marshes, and the most unhealthy part of London;" at Ilfracombe, "it is damp from blowing down the Channel;" at New York, it is "loaded with vapour from the Atlantic;" at Niagara, "it blows over swamps and lakes;" at By-town, in Canada, "it blows over such an extent of dry land and forest, that it brings with it miasma from decayed vegetable matter." Now, as far as I myself am concerned, I can only say, that whatever part of the world I may be in, I can tell, even while in bed, in a closed room, when the wind changes to the east; that as long as it lasts I have neither appetite, strength, nor spirits; and that in a couple of hours after it changes, I experience the same relief as I have often done when stepping from the deck of a steamer, after a rough passage, on terra firma. That it produces the same effects on animals, can at any time be proved by dividing a field, and putting up a shed in each portion, one facing the east and the other the west; then turn a cow, horse, and sheep (as nearly as possible alike in age and condition) into each portion, and after a single month of "easterly," the difference in condition will be apparent to a tyro. During its prevalence you will see the animals in the shed open to the west go out, feed hastily, and return to their shelter, while those in the shed open to the east will be uneasy, and if there be a wall, hedge, or ditch on the opposite side of the field, there they will be found. It is also worthy of note, that the east wind when mentioned in scripture, is generally associated with some calamity.—*Letter in Lancet.*

LUPUS CURED BY COD-LIVER OIL.—*L'Union Médicale* mentions a case of lupus in which the ulcerations cicatrized under the influence, or during the administration of, enormous quantities of cod-liver oil. The patient was a young man, aged 23, residing in the country, and was admitted into the hospital of Ghent on the 6th of December, 1850. The disease had manifested itself in various parts of the face and chest, and was of old standing. After purging and rest, half a pound of oil was given in the day, two equal halves being taken morning and evening; the daily dose was gradually carried to three pounds, with occasional interruptions when the appetite failed or diarrhoea came on. The patient was in the meantime well fed, had wine and beer, and the ulcerated spots were successively touched with tincture of iodine, lemon-juice, and nitrate of silver. In the space of about seven months the cure was complete, all the lupoid ulcerations, to the number of three or four, were completely cicatrized, and the patient had purchased this result by swallowing during that period 265 pounds of cod-liver oil.

**TO DENIS JOSEPH HYNES, ESQ., M.D.,  
 KINVARRA.**

DEAR SIR,—We, the undersigned members of the Medical Profession connected with the medical charities of this and the neighbouring counties, desire to tender you our sincere acknowledgments and thanks for the exertions you have on all occasions made to uphold the dignity, the honour, and respectability of our profession.

Your attendance as a Provincial Representative of our body on the Medical Charities Committee in Dublin, and your anxiety, as evinced by your published correspondence with Sir William Somerville, to render the bill as acceptable as possible to the profession at large, deserve our highest commendation.

Adverting to a correspondence which has lately appeared in the DUBLIN MEDICAL PRESS, as having taken place between you and another member of the profession, and duly weighing the facts of the case at issue, as disclosed by that correspondence, we feel that we would not be discharging our duty, either to you or to ourselves, did we not come forward to express our entire approval of the course you have adopted on the occasion.

Feeling that a principle most vital to our interests was involved in that controversy, we have no hesitation in saying that you, by your sincere and steady advocacy of that principle, as well as of the interests of the profession in general, have earned the approbation and good opinion of all your professional brethren.

(Signed)

Answer.

GENTLEMEN,—Your very flattering address conveyed to me through my esteemed friend Dr. Suffield, and for which I sincerely and heartily thank you, is proud evidence of the fact, that however humble be the individual in our profession whose conduct and acts tend to uphold, to the best of his ability, the honour and dignity of his profession, he will be sure to earn for himself, in the approbation and thankfulness of his professional brethren, that reward to merit which should be the aim and pride of us all.

That my humble efforts in the cause of my profession should have called forth the expression of your approbation, is to me a source of pride and pleasure at the same time; and when I recognize in the array of signatures attached to your kind address the names of all those in this side of the country whom I have usually found engaged for the last two years in the promotion of the welfare and independence of their profession, the complimentary terms in which the approval of my conduct is conveyed in that document, become, on that account, doubly valuable to me.

I have only to add, that the consciousness of having "earned (as kindly expressed by you) the approbation and good opinion of my professional brethren," will act as a further stimulus to me in my future career to maintain that good opinion by every act of mine, and on every occasion in which the interests of our noble profession may be at stake.

I have the honour to be, with many thanks,

Your grateful and faithful friend,

Kinvarra, May 7, 1852.

DENIS J. HYNES.

**SCHOOL OF SURGERY.**

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**

THE Summer Courses of Lectures commenced on Monday, the 26th of April, when Lectures on the following subjects were delivered, in accordance with the regulation of the Council of the College:—

Materia Medica	...	...	Dr. Williams.
Medical Jurisprudence	...	...	Dr. Geoghegan.
Practical Chemistry	...	...	Dr. Barker.
Botany	...	...	Dr. A. Mitchell.

Examinations will be held, and Premiums awarded to the successful Candidates, at the termination of the Session.

**DISEASES OF THE EYE.**

**SUMMER SESSION.**

DOCTOR JACOB commenced his Lectures on DISEASES of the EYE, in the City of Dublin Hospital, on Tuesday, the 18th of May, and will continue them during the SUMMER SESSION, so as to form a complete Course of OPHTHALMIC SURGERY.

**CITY OF DUBLIN HOSPITAL.**

**SUMMER SESSION.**

THE Clinical Lectures and other forms of Instruction commenced in this Hospital on the 26th of April. By a recent Ordinance of the College of Surgeons, separate Certificates of Hospital Attendance, during the SUMMER SESSION, are required.

**CITY OF DUBLIN HOSPITAL.**

THE HOUSE-SURGEONCY of this Hospital will be vacant upon the 25th inst., when the Election of a Gentleman to fill the Office will take place.

Candidates must have received the whole, or a portion of their Education, in the Hospital, and a preference will be given to such as are Licentiates of the Royal College of Surgeons in Ireland.

Application, with testimonials, to be made to the Secretary, Dr. Benson, York-street, Dublin, on or before the 24th inst.

**MEDICAL BENEVOLENT FUND SOCIETY OF  
 IRELAND.**

THE Annual Meeting of this Society will be held on Monday, the 7th day of June, in the College of Physicians, Grand Canal-street.

The President of the College will take the chair at four o'clock p.m.

Members of the Society are particularly requested to attend, and to prevail on non-subscribers to accompany them, that they may be made acquainted with the objects and operations of this invaluable institution.

By order,

W. KINGSLEY, } Hon. Secretaries.  
 C. BENSON, }

May 18, 1852.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

**THE COMPOUNDING DEPARTMENT AT**

**G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

J. H. Whiteway, Esq., Lincoln's Inn Fields.

Those marked with an asterisk being Medical Examiners to the Society.

*Auditors*—John Brown, Esq., Surgeon, Hammersmith; George Carew, Esq., Lincoln's Inn Fields;  
F. W. Remnant, Esq., Lincoln's Inn Fields; and E. Ray, Esq., Surgeon, Dulwich.

*Bankers*—Messrs. Praed, Fane, and Co., Fleet-street. *Standing-Counsel*—Thomas Webb Greene, Esq.

*Solicitors*—Messrs. Pooley, Beisley, and Read, Lincoln's Inn Fields.

*Secretary*—Frederick James Bigg, Esq., 126, Strand, London.

This is the only Society in connexion with either the Medical or Legal Profession, founded on the principle of **MUTUAL ASSURANCE**.

This principle is the most beneficial to the Assured, amongst whom **THE WHOLE NET PROFITS ARE DIVISIBLE**. The Society has a Subscription Capital to guarantee the prompt settlement of claims.

The business of the Society includes—

**ASSURANCES**, on a Single Life, with or without profits; also on Joint Lives, and on Survivorships.

**ANNUITIES**, for Lives and Limited Terms, Immediate, and on Survivorship.

**DEFERRED ANNUITIES**, with the privilege to the Grantees of receiving, in lieu thereof, either their present value in money, or a policy for the equivalent sum at death.

**ENDOWMENTS** for Widows and Children.

The Society also offers new and distinctive forms of Assurance; as—

**ANNUITIES TO CHILDREN**, payable from the death of a parent or other person, or for a stated number of years, commencing at a given age.

**ENDOWMENTS** at all ages.

**AND ALL OTHER** sound and practicable **PROVISIONS** contingent on human life, or for terms certain.

**INVALID** Lives Assured at equitable rates.

### ADVANTAGES OFFERED BY THE SOCIETY.

**THE RATES OF PREMIUM**, which are founded on the most accurate observations of the duration of human life, are as moderate as is consistent with due Security.

**PREMIUMS** may be paid either Yearly, Half-yearly, or Quarterly, or in a single payment, or in a limited number of payments, or by an increasing or decreasing scale; or half the Premiums may remain unpaid at simple interest for the first Seven Years, and may be then paid off, or remain as a Debt upon the Policy, at the option of the Assured.

**MILITARY AND NAVAL OFFICERS** Assured at the ordinary Rates, until called into actual service.

**THE AGE** of the Life Assured will at any time be admitted on satisfactory evidence being produced.

**CLAIMS ON POLICIES** will be paid within Three Months after satisfactory proof of Death shall have been produced.

**NO ENTRANCE OR ADMISSION FEE**, or other Charge beyond the Stamp of the Policy, which may be commuted by a small Annual Payment.

**ANY MEMBER** wishing to dispose of his Policy, the Directors will purchase it for a sum of Money, payable immediately or at his death; in which latter case the value will be secured by the grant of a New Policy, without further payment, to rank in date as a continuation of the Old Assurance in the future division of Profits.

### PREMIUMS FOR ASSURING £100 AT DEATH.

WHOLE TERM OF LIFE.						
Age	With Profits.		Without Profits.			
	Annual Premium.	Single Premium.	Annual Premium.	Single Premium.	Seven Years.	One Year.
15	£1 10 10	£33 6 10	£1 7 10	£30 0 3	£0 16 9	£0 16 0
30	2 6 2	44 2 9	2 1 7	39 14 7	1 5 8	1 3 2

And so on in proportion up to age 70.

Prospectuses, Forms of Proposal, and every further information, will readily be supplied on application, either personally or by letter, to the Actuary, or to any of the Society's Agents.

### MEDICAL REFEREES.

HENRY L. DWYER, M.D., 67, Upper Sackville-street: WILLIAM STOKES, M.D., Merrion-square.

A Liberal Commission to Solicitors and Agents.

### EDINBURGH PHYSIOLOGICAL SOCIETY.

#### ON THE MOLECULAR ORIGIN OF THE TISSUES.

By Dr. BENNETT.

THE great generalisation of Schwann was that all tissues are derived from cells. Subsequently, it was ascertained that the nucleus, or cell-germ, exercised an influence on the tissues, independent of its cell wall; and it was endeavoured to be shown, that some tissues might be derived directly from nuclei. The object of this communication was to point out that the nuclei themselves originated from smaller bodies—viz., molecules; that these were the origin of every texture, and to indicate some of the laws which governed their formation, arrangement, and subsequent development. From a review of the observations of Schleiden, Schwann, and Martin Barry, the author pointed out how the first appearance, observable in all developing organisms, was a mass of molecules and granules, which, by aggregating or melting together, constituted the cell germ. Around the cell germ other molecules were formed, which again, by melting together, constituted the cell wall. Further development, in like manner, proceeded by the apposition of molecules. At any period in the process of evolution, the onward progress might be checked when the structure became disintegrated in the inverse manner to its formation: First, the cell wall became dissolved, then the nucleus, both of which were reduced, first to molecules, then to a fluid. Hence there were molecules of evolution and molecules of disintegration. Occasionally, between the cell wall and nucleus, secondary molecules were formed, which constituted peculiar secretions, as they have been termed: these might be called molecules of transformation. The author described the origin and mode of formation of these three kinds of molecules, their physiological and pathological importance, and pointed out the advance which had been made in our knowledge of molecular formation by the observations of Ascherson, Harting, and Melsen. In complex organisms, the higher tissues were formed by an elaboration of blastema, mainly due to the successive evolution,

transformation, and disintegration of matter, by means of the three different kinds of molecules, of which the author gave numerous examples, derived from the elaboration of the ovum, of the blood, the transformation of insects, the process of fissiparous division in the lower animal forms, &c. He pointed out that molecules had independent movements, sometimes physical, as in the case of Brown's molecular movements, at other times vital, as seen in many organisms. That occasionally we had molecular fibres, from the aggregation end to end of molecules, in the same way as we have nuclear cell fibres. Moreover, each kind of fibre could assume inherent contractility, as in the case of vibriones, which might be called contractile molecular fibres, as spermatozoa might be denominated contractile nuclear, and cilia contractile cell fibres. The author concluded a lengthy communication by remarking, that not only did a study of the molecular element indicate the origin and development of healthy and morbid product, but it pointed out the basis on which a rational treatment was to be founded, as far as diseases of nutrition were concerned. Thus in tubercular diseases, where molecules of evolution were deficient from absence of the fatty element in the chyle, animal oils were indicated to favour the production of such molecules. When the blood was diseased, in cases of gout, rheumatism, rachitis, scurvy, &c., such morbid conditions could only be removed by the introduction of substances which either directly or indirectly, physically or chemically, favoured the production of certain molecules of transformation, as those in the blood; and when any of the tissues seem redundant and hypertrophied, tumours constituted the morbid condition; thus the cure would depend on the discovery of those means, whereby granules of disintegration might be induced and subsequently eliminated.

#### ON PATHOLOGICAL CELL DEVELOPMENT.

DR. GAIRDNER made a verbal communication of considerable length, on certain peculiarities of pathological and other structures, as bearing on the different theories of cell development. He considered the cell theory of Schleiden and Schwann, although it led to the discovery of many in-

interesting facts, and really important morphological generalisations, to have been utterly overthrown, as a general theory of development, by the progress of scientific inquiry. The "cell" of these physiologists, so far from having the fixed and uniform character of a basic type of form, was the most fluctuating and uncertain of all morphological creations. Its form, size, law of development, were either confessedly uncertain, or had to be stated in terms so vague as to lead to the conclusion that form and substance, and perhaps microscopic size, were the only attributes essential to the idea of a cell. No one could tell, in practice, what was a cell wall and what was a nucleus, and no one could give a satisfactory theoretical definition of either, or resolve, for all cases, which of the two preceded the other in the course of development. The theory of "germinal centres," held by Mr. Goodsir, in so far as it ascribed to certain "nucleated particles" the function of the cell, was, in Dr. Gairdner's opinion, subject, in like manner, to the imputation either of vagueness or of want of comprehensiveness. If these nucleated particles came under any more precise definition than was applicable to every kind of organic or inorganic structural atom, it would be very difficult to show that they monopolised and centralised the whole functional activity of the organism, or were more necessary than other parts to its growth and preservation. He (Dr. Gairdner) believed that there was no distinction in the organism of passive and active atoms, and considered every point and every molecule as endowed with its own life, and placed, in its own peculiar sphere of activity, in harmony with the rest. He agreed with Dr. Bennett in thinking, that many tissues arose from elements far more minute than any to which the term cell or nucleus had been applied; indeed, he was far from thinking that our microscopes had conducted us back to the real germs of the tissues, and considered that the structural, like the chemical atom, still lay in the remote region of hypothesis. He firmly believed, however, in these hypothetical germs, and could not conceive of the tissues being formed by any thing like what the Epicureans would have called a concourse of atoms, according to their physical and chemical properties. Hence he did not think, that by the mere introduction of peculiar molecular elements into the food, we could either create new tissues or destroy old ones, so directly and simply as had been hinted by Dr. Bennett. The positive part of Dr. Gairdner's communication consisted in the detail of observations on the structure and development of the pus corpuscle and other pathological structures, intended to show that the so-called cell walls were often generated in great numbers without nuclei; and that the whole of the facts of cell development contradicted the idea of any part of a cell being, more than another, the source of its functional activity and development. In regard to the development of fibres, Dr. Gairdner thought there was no evidence that these were ever produced from cells, under any circumstances; and he had long been in the habit of regarding the so-called fibre cells as merely transition types in morphology, and not parts of a physiological succession of stages of development. It was difficult to prove this view any more than its opposite, but he thought any one who would give it consideration in original observations, would find it in harmony with all the known facts, both physiological and pathological.

Dr. SANDERS remarked, that Kölliker had demonstrated unstriated muscular texture to be composed of permanent fibre cells, whose development by elongation of spherical nucleated cellules he had traced in the pregnant uterus. This texture, therefore, had been lately found a corroboration of Schwann's views, which it was previously thought to contradict. Doubtless some textures were formed without passing through the form of cells; thus, particularly, fibrous tissue, as observed in cartilage by Redfern and Donders; yet the constant presence of nuclei and cellules in skin, mucous membranes, glands, and bone; their transition forms; their extensive development in the fetus; their occurrence in newly forming textures in all organized beings, animal and vegetable, gave immense weight to Schleiden and Schwann's views, and justified

our adherence to them in physiological anatomy. In pathology, their application appeared more limited, and less satisfactory. Dr. Gairdner's statements, and a gaining distrust among observers at home and abroad, proved the necessity of submitting the "cell theory" to the criticism of new and extended observations; it ought not, however, to be rejected, but only thoroughly reinvestigated.

#### STRUCTURE OF ARTERIES.

Mr. DRUMMOND exhibited several preparations of the middle coat of the aorta in the ox, for the purpose of showing—1st, that many of the fibres present a distinctly transverse striated appearance. They are branched generally, and anastomose with neighbouring fibres, presenting an appearance very similar to the branching striated muscular fibre, seen in some of the Insecta. From muscular fibre, however, they differ in their chemical constitution, agreeing in this respect with yellow elastic tissue. They are in all probability analogous to the striated fibres occurring in the ligamentum nuchæ of some animals. When viewed with a high power, many of them seem to present a series of cup-shaped depressions, arranged in linear series in the longitudinal axis of the fibre, with intervening ridges or partitions, to which the striated appearance is owing. 2nd. That the structure described under the name of the fenestrated coat of Henle, as it occurs in the middle coat of the aorta in the ox, is formed by the amalgamation of the network of the yellow elastic fibres, the fenestræ or perforations being merely the remains of the areolæ between the fibres. The fibres which go to the formation of this coat often present traces of the transverse striated appearance above described. Preparations were also shown illustrating the development of the yellow elastic tissue as it takes place in the ligamentum nuchæ of the calf. A description of the development of this tissue will be given in a future report.

Dr. BENNETT showed, under the microscope, demonstrations of the blood in a case of leucocythemia, in the practice of Dr. Monro of Dundee.

Dr. GAIRDNER exhibited various organs, as well as the clot of the blood, and a slightly enlarged and softened spleen, in what he considered as an incipient case of leucocythemia, probably the earliest stage of the affection yet observed. The patient died of acute rheumatic endocarditis, with disorganization of the aortic valves and septum ventriculorum. The tissues, the blood, and the spleen, contained an excess of white corpuscles.

Dr. SANDERS was requested to investigate the spleen in this case.

#### DEVELOPMENT OF PUS CORPUSCLES.

Dr. SANDERS reported some observations on the corpuscular contents of the vesicles of small-pox. On the fourth day of the eruption, the fluid of the vesicle presented some clear, gray nuclei, about the size of blood corpuscles, and showing only one or two granules in their interior when acted on by acetic acid. On the fifth and sixth days these corpuscles had increased in size and numbers, and become more granular; the amount of free molecules and granules, at first very scanty, was now greater. On the sixth and seventh days, nucleated cells, spherical, and more or less granular, occurred along with the corpuscles before described; and a few large cells, of the diameter of four to five blood discs, and containing several nuclei imbedded in granular matter, were also observed. The corpuscles, however, were the chief elements; they were granular, like the usual pus-corpuscles, and presented under the action of acetic acid, some a triple nucleus, others several granules. From this stage, when the fluid was distinctly purulent in its characters even to the naked eye, up to the time of scabbing, or twelfth day of the eruption, the changes were a gradual increase in the free granular matter, and a diminution in the amount of corpuscles, which at last gave place to the granular matter; which last, along with epithelium cells, dried up to form the scab. The fluid of the vesicles therefore exhibits a process of cell growth from nuclei to pus corpuscles, and nucleated cells, which become

more and more granular, and break up at last into free granular matter. The so-called pus-corpuscles are a stage in cell formation. Considering the small amount of granular matter, both free and within the corpuscles at the beginning, and its great abundance subsequently, the author was disposed to doubt the formation of these corpuscles and cells by the aggregation of granules subsequently surrounded by a cell wall, but regarded the granular matter rather as a production of cell growth.

Dr. SANDERS also communicated the following

#### ON THE CONTENTS OF THE CYST IN A CASE OF RANULA.

In the fluid contents of a ranula existing on the left side of the tongue, and evacuated by incision, the liquid was transparent or slightly opalescent, viscid, and tenacious, and forming a thick, curdy precipitation on the addition of nitric acid. Under the microscope (250 diam.), a large number of cells were seen in different stages of growth; the most numerous about 2.3 centimillimetres diam., granular, generally with one, sometimes two, nuclei. Some larger cells, of 4.5 centimillimetres, contained several, sometimes four or five, clear, shining nuclei, imbedded in granular matter in their interior. On dilute acetic acid being added, the nuclei became more distinct; and in the larger cells, the granular matter, with its imbedded nuclei, contracted into a mass, and separated from the cell wall, leaving it clear and projecting, like a watch-glass, at part of its circumference. A curious phenomenon was also noticed; several clear, spherical, colloid processes were developed at the circumference of many of the cells from which they appeared to proceed.

Mr. DRUMMOND mentioned, in opposition to the assertion of Zimmerman, that the blood of the fetus contained no fibrine, that he had recently found it to contain a considerable quantity of that substance.—*Edin. Monthly Jour.*

#### MISSISSIPPI VALLEY ASSOCIATION OF DENTAL SURGEONS.

Dr. ULREY read a paper on the subject of

##### ATMOSPHERIC PRESSURE PLATES.

Dr. J. TAYLOR remarked that he had been depending more upon this principle for sustaining plates within the last year than formerly, and believed his practice during that time, in this particular, had been more successful. He did not confine himself to any particular form of chamber, but varied it according to circumstances. He had made chambers by enlarging the ruga, had formed the Flagg chamber, and, indeed, had tried all proposed forms. He, however, preferred the chamber in the centre of the arch. He usually made the one he prefers by placing some wax on that portion of the plaster model, and trimming it to about the thickness of a dime, leaving its edge acute. In this way he was able to strike up a chamber at the same time he struck up his plate, and no soldering was required about it. He has, during the past year, been using plaster as the substance to take his impressions, and thought his better success during that time was owing to that fact; and he would recommend it to the Society as a thing altogether superior to wax for impressions. He knew it was more difficult to use at first, but if gentlemen would stick to its use in full upper sets, in a short time they would not abandon it. He had made out to take some under impressions with it, but here, and in partial sets, he generally uses wax. In using plaster, he places a rim of wax across the back of the holder; in the centre of the impression, before its removal, and after it has set, he inserts a probe, which allows the air to pass into the arch; then immediately the impression may be removed. He did not think salt necessary in using plaster to make it set quick.

Dr. ALLEN preferred wax as a substance to take impressions. He had tried all the various chambers. He had found those on the ridge very serviceable. He had constructed some under the front teeth, that worked well. He thought an advantage arising from the use of chambers on the ridge, to be the overcoming of some of the evil results of soft spongy gums. He preferred to form the

plate by striking up the chamber and plate in one piece, as followed by Dr. Taylor. He usually made the plate as large as possible, believing that the larger it was the better it would hold; but he held that much depended upon the articulations of the teeth, whether or not the work would be serviceable. Many failed by setting the teeth too far outside the ridge. He had frequently to correct the work of his young men in this particular, and he thought it a point too much overlooked generally. Dr. Taylor seemed to consider a chamber an essential part of atmospheric plates.

Dr. GODDARD's views being called for, he said he did not know anything about it. He thought it a mistake to make plates as wide as we had been in the habit of making them the last few years. He had found that wide plates, after being worn for some time, would be found bearing hard upon the centre of the arch, creating thereby a rocking motion of the plate; the result, as he conceived, from the wasting of the ridge. He is now using the old-fashioned moderate-sized plate, which does not cover all the hard palate. He prefers wax as a substance for the impression.

Dr. TAYLOR had also found the rocking motion from undue pressure on the arch. He had tried to obviate the difficulty by adding some wax at that part of the plaster model before making the plate, but it did not overcome the difficulty. He therefore inclined to the opinion that plates were frequently made too wide, and that we had better make them, in some cases, as Dr. Goddard suggested. He agreed with Dr. Allen in the principle stated, that pressure is generally according to the surface, but he thought the plate should not extend further behind the chamber than sufficient to give a bearing to the edge of the chamber, and prevent its being forced into the gum. In answer to a request that he would explain, on scientific principles, the mode upon which the partial vacuum in the chamber is obtained, he said he did not know that he could give a full explanation of the thing. About all we know is, that, some how or other, it was done by the wearer applying the tongue and sucking out a portion of the air. In answer to another query, he said he used the plaster about the thickness of cream. He was further asked, how, in that case, he got the impression of a mouth with a high arch? There was always a portion of plaster in the bottom of the cup a little thicker; this he removed, and with a spatula placed it in the elevated portion of the arch, he then inserted his holder containing the balance. As an instance, in proof, that a narrow plate would sometimes be preferable, he stated that he had lately been called upon by a lady having a temporary upper set which was not a good fit. She wished a set inserted on the pressure principle. He took an impression, and the first trial obtained a plate requiring some ten or twelve pounds weight to dislodge it by a direct pull. He attached the teeth, and inserted it to his own satisfaction, but practically they did not suit the lady. If she attempted to bite with the front teeth, the back part of the plate would drop; still she could use the old set in this way without that effect, although a little direct force would dislodge them. He made a second and a third set, but without making them preferable to the old one; he then concluded to make a plate just like the old one, which was narrow; he did so, and they proved more satisfactory.

Dr. LESLIE remarked that to him this was an interesting subject, for he had never been able to agree with the majority in the views they held. This is a matter which has occupied the attention of the profession through our periodicals and otherwise, quite largely, and for a length of time, and he had watched the development closely. Conscious that his views differed, he has endeavoured to sift the views of others on this subject, in order that the searching might, if possible, clear up any mistakes he himself may have made. This it was, also, that pointed the queries addressed to Dr. Taylor. I have always been a questioner of the advantages of cavity plates. Hence, whenever I have met with gentlemen who claimed experience in the use of them, I have put such questions as I did to him. I claim not to have had much practical

experience in the use of the cavity, simply because I have never been able to convince myself of their advantage, or to have been so fortunate as to be so enlightened by others; hence my course; and if I am pointed in my remarks, it is simply that I may convince, or be convinced of my error. My own view of the matter is, that cavities in atmospheric plates will ultimately be abandoned. I found this opinion on the fact, that, with but one exception, the arrangements of this nature are unscientific in their construction, and that a vacuum cannot be formed in any of them, unless they possess the valve of Dr. Dwinelle. They then become the exception which may be considered scientific in its construction. I have asked Dr. Taylor, as I have others, to explain how even a partial vacuum can be formed in the cavities he and they make use of; and I have found that when the difficulty of explanation was not immediately perceived, it was at least felt, and the most I have obtained was, that they judged by the effects the cavity produced in some cases upon the gum, that a portion of the air was exhausted; secondly, that such plates adhere more firmly than those without the cavity, and they consequently conclude the air was got out by suction. Now, I think that gentlemen allow themselves to be led astray by appearances. I conceive it to be no proof that there has been a partial vacuum in a cavity, because you find on removal of such a plate that the gum over such cavity is swollen. This may be the result in a mouth where the gum is in any way spongy if having a cavity there. That portion presented to the cavity is not subjected to the pressure the portion is which the surrounding plate lies in close contact with; it is, therefore, left free to develop fully its spongy tendency by protruding into the cavity; and this tendency, be it noticed, is increased by the surrounding pressure. So that you see, I must take part of their evidence, and claim it as another proof that the cavity plate must be abandoned. I hold further, that cavity plates must be abandoned, even were I wrong in assigning the swelling of the gum into such cavities to the absence of pressure there; because I hold that if there is a vacuum, be its degree what it may, the tendency must inevitably always be for the gum to fill up the cavity; and I feel assured by analogy, that where the means exist of forming a vacuum in such cavities, the gum would ultimately fill them up, unless such means of preventing it are adopted in Cleaveland's chamber, which may be viewed as a chamber beyond the ordinary chamber, having very small openings into the second; which arrangement the patentee himself says is to prevent the gum swelling so as to fill up the second chamber. This clearly proves one of my positions—that if a vacuum be obtained in ordinary cavities, it will in time be filled up by the gum. If we examine the actions of an air-pump exhausting the air from a vessel on the lecturer's table, we perceive he attaches the pump to a truly turned metallic plate, in the centre of which we observe a small opening which communicates with the pump-chamber. We understand at once the object of it: it is for the egress of the air. If the edge of the glass vessel is not perfectly true, so as to form a perfect joint with the plate, he uses a rim of buckskin to effect this—so essential is it that the edges of his cavity should fit close all round when he commences exhausting their chamber. Not so the dentist who uses the cavity; he tilts the vessel (cavity) to one side, and "sucks" the air out. We have another illustration of the partial or complete exhausting of a chamber in the act of cupping. These cups, in which the air-pump is used to exhaust the air, have a valve on the top, and we see at once how the air may be exhausted—it is done precisely on the principle of Dr. Dwinelle's chamber. We have also the old-fashioned cup, in which a flame is inserted for the expulsion of a portion of the air. Here again we see the mode. Not so in the cavity practice; and until we are shown a better explanation than has yet been given, we must hold that they have not any more pressure by means of the cavity than can be got without; and I question if they have as much as exists in a well-formed plain plate. A question, which I think of some importance to determine nearly

as we can, is, what amount of atmospheric pressure is requisite on an upper set of teeth, in order that they be useful? Some men there are who promise their patients from five to twenty pounds, as it may be desired, or as they think the case demands. To hear them talk, one would think it was as easy to do this as to make the chamber. But, for my part, I never say anything of pounds to my patients, all I promise is a useful set of teeth; this is all that is needed. It may not be startling enough for a striking advertisement, but as I never aim at such things, it matters not to me. I trust always to redeem my pledge by using the plain plate; and here let me say, that it must, I think, be within the power of all dentists of experience to refer to sets of teeth they have inserted with the plate, void of any cavity, which gave entire satisfaction to the wearer without the aid of springs; and I believe it may be said of such cases, that they are preferred by the wearer as well as the operator, to those with cavities. The amount of pressure on a well filled and properly articulated set of upper teeth, need, I think, but little exceed the actual weight of the operation and the pressure exerted by the tongue in articulation. Where the plate is properly adapted, and there is anything of an arch in the mouth, and the plate can be brought over the ridge, mastication but increases that pressure on the exposed surface of the plate. Of such a plate, of course it is a pre-requisite that it should stand pressure in any part, without dropping at the opposite point. We all know that some plates we make take hold, so to speak, of the gum better than others. This irregularity is attributed by some to various causes, peculiar form of the mouth, sponginess of the gum, &c. When I meet with a plate that does not stay up, I lay it to myself, not to the mouth, to a failure in my impression, and set about taking another. I do just the same when it rocks on the centre of the arch; I view it as my fault. I may have failed in gaining the impression from pressure against the lips in removal. I think more harm results from these soft parts than from those on the ridge, which some gentlemen fear so much. Having obtained a good impression, I consider there is no difficulty in making a plate which will be retained by atmospheric pressure. This atmospheric pressure I conceive to be obtained by an approach to a perfect adaptation of the plate to the mouth. The more perfect this is, the greater the pressure. Such a plate, when placed in the mouth and forced against the gum, displaces the air that is in contact with that surface; and thus the balance of pressure is created upon the exposed surface of the plate, and this it is which retains it in place. Hence, simple occlusion of the jaw is sufficient to restore the pressure when the plate inclines to drop. This, I conceive, to be the true theory of atmospheric pressure, as applied in dentistry. Consequently, I cover as much surface as possible when I want this pressure. This is in accordance with the well-known principle alluded to by Dr. Allen, that the pressure is according to the extent of surface. It is in accordance with this theory, which I have endeavoured to develop, that I conceive the artificial enlargement of the ruga, and all forms of chambers not possessing the valve of Dwinelle, as worse than useless, from said cavities being reservoirs of air, by which the plate is sooner separated from the surface of the gum; and as a matter of course, if the air is not partially exhausted from the chamber, there is not as much pressure on the plate as if it was not there. I object, then, to the use of chambers—1st, because they are not what they are supposed to be, partial vacuums; 2nd, that if they were, they would to that extent produce swelling of the gum into the cavity; 3rdly, because they are unnecessary, the simple plate being sufficient. I throw these thoughts out, observing, that if there be error in them, it will be shown by those who perceive it. Next, a word or two on the impression. It is claimed by those who prefer prepared gypsum as a medium to receive an impression, that its chief advantage consists in the perfection with which they obtain an impression of the soft ruga and spongy ridges, without any displacement of the soft parts, there

being no pressure required in its use; while in the use of wax, these parts are more or less displaced. Of plaster, I would say, that if it were possible to use it under circumstances requisite to its most perfect application, that it would undoubtedly be preferable. But I have yet to learn how it may be so managed. To obtain with it a perfect impression, it should be used as thin as the medallion maker employs it. This is much thinner than Dr. Taylor employs it. You will now perceive the force of my inquiry of the doctor as to how he obtained an impression of the elevated arch. Here he finds it necessary to use, shall I say, a piece, it would be near if not quite the truth: at least it must be considerably thicker than cream. I had thought, and still do not see otherwise, that plaster should be used just as it begins to set; because if used in the liquid state, it must follow the law of liquids—viz., seek a level. Now, I question whether in either of these states, a more perfect impression can be obtained with it than with wax. Again, is it a fact that it can and is used without any pressure? If so, a steady hand must sustain the holder, an equally steady one the patient's head, as the least motion during the setting of the plaster must change the impression. I will frankly acknowledge, that with wax it may be impossible to get an absolutely perfect impression. But I think that with proper care, your success will be quite as great with wax as with plaster as now used, and while the advantage is clearly in favour of the plaster, the simplicity of wax must give it the preference. I make use of pure yellow wax, softened in water, not above 140 deg. F. It should never be allowed to melt in the surface. It is also best to use it but once, it is then tougher, not to mention cleanliness. Another thought which has been presented, of which I could not see the philosophy: it has been asserted here, and I have heard of it elsewhere, that if you insert a probe through the plaster or wax until it touch the elevated portion of the arch, you could immediately remove an impression, which, without such a course, would have been destroyed by the force necessary to remove it at the same period. I say I cannot understand the working of the probe. It may be ignorance, but it appears to me that if I was to fill a vessel with wax or plaster, and turn it bottom up, and insert a probe such as the gentlemen uses, it would only allow air to pass to the surface the probe touched. By what means the air is to pass between the vessel and the wax, or between the gum and wax or plaster radiating from the small opening, I cannot so clearly see, especially as its effects are said to be immediate. If it were claimed to be a slow process, I would admit it may be of some utility; or if the plaster or wax had not been placed in close contact with the highest portion of the arch, I could see how the external opening would operate upon the confined air in that cavity, but in the way claimed I cannot. I could see how, if it were such a fluid as water that filled the supposed cup or arch of the mouth, that the insertion of a tube which would pass air to the upper surface would radiate immediately over said surface, because in this case the fluid would immediately descend, not so in the other. In my own practice, consequently, I make no use of the probe. Not because my impressions do not adhere as firmly as those of others, but because I conceive the mode I adopt of overcoming the difficulty as superior. My mode of procedure is based upon what I believe to be a fact,—viz., that the soft parts (buccinator muscle and mucous membrane) act the part in the impression that the rim of buckskin does under the air vessel. It makes the adaptation more perfect. My first step in accordance with this view, after the wax has set is to raise these soft parts, first on one side and then the other, repeatedly if necessary, allowing the air in this way to gain access to the whole rim of the impression. The result I find to be that an impression which before would have been destroyed in the attempt to remove it, now may be removed safely. I can feel it give way. In the language of others, "it will presently drop."

Dr. GRIFFITH said he had been in the habit of using the probe, and found it very serviceable.

Dr. TAYLOR admitted that the soft parts named by Dr. Leslie played an important part in the adhesion of the impression, and he always raised these also, as Dr. Leslie had described. Still he contended that the probe was indispensable, and that the air did pass from the opening it made over the surface of the arch. He was certain his views respecting the great advantage plaster had over wax would be found to be sustained, if gentlemen would try it more. One thing he would say for it, and that much he could not say for wax. He would undertake to get a plate that would stick to the mouth from the first impression. If he could not do this with any mouth, he would forfeit fifty dollars. He, however, believed the day was approaching when cavities would be abandoned, and the simple plate be proved sufficient for our purpose; for he must say that he had inserted many sets without the chamber, and that on the whole he and his patients preferred such, when he could get them, to those with the chamber.—*Amer. Jour. of Dental Science.*

#### PROTRUSION OF THE EYEBALL, PROBABLY FROM AN ENCYSTED TUMOUR IN ORBIT.

Dr. HAYS remarked, that if there was nothing of more importance to occupy the attention of the College, he would take the opportunity of relating the outlines of a somewhat curious case that had been interesting to him, and he thought might be so to the fellows present. He had been sent for, in April last, to see a lady from the State of New Jersey, about 35 years of age, of lymphatic constitution, who was labouring under a very considerable protrusion of the right eyeball, which was rolled inwards towards the internal canthus: the upper eyelid was greatly enlarged by a number of encysted tumours within it. The deformity resulting from this condition of the eye, as may readily be supposed, was very considerable; the sight of the eye was entirely gone. Dr. Hays was unable to obtain any very satisfactory history of the case. The patient was an orphan, and from her brother, who was but a few years older than herself, all that could be learned was, that from his earliest recollections of his sister her right eye was somewhat protuberant. He thinks that he had heard her parents say, that up to her fourth year she had had no affection of her eye, but soon after this period the swelling had commenced, and had gradually increased, until it had attained its present magnitude. The physicians in her neighbourhood had been consulted in her case, and had tried a variety of remedies for her relief, but without success. She had finally been brought to Philadelphia for the purpose of consulting Dr. Hays, who could not discover anything in the case to lead him to suspect that the protrusion of the eye was caused by the formation of a malignant tumour behind it; he suspected that it was caused either by an encysted tumour behind the ball, or by an effusion within the capsule of Tenon. Still he was not sufficiently positive as to the correctness of this diagnosis as to warrant him in the introduction of a bistoury with the view of causing the discharge of the effused fluid. He concluded therefore to first direct his attention to the removal of the cysts within the upper eyelid, in the hope that, in the course of his attendance, the correctness of his diagnosis would be confirmed or disproved. One of the cysts was opened with the knife, and then solid sulphate of copper was applied to its inner surface. The others were treated in succession in the same way, and the tumefaction of the lid, in consequence, was considerably reduced. At this state of the case, Dr. Hays left for Charleston to attend the session of the American Medical Association. Upon his return he was sent for, and then learned that on the day he left, the patient had accidentally tripped over, and in falling, had struck with violence the right eye against the edge of a chair. The pain was intense, and the consequent swelling, from the contusion and ecchymosis, very considerable; upon the disappearance of this, it was found that the protrusion of the eyeball had greatly diminished. Dr. Hays thought that very little doubt could exist as to the mode in which the violence inflicted upon the eye, in this case, had

caused the removal of the protrusion previously existing. It was evidently by the rupture of the cyst or of the capsule of Tenon and the consequent escape of the fluid into the cellular tissue of the orbit where it had been afterwards absorbed. Had the protrusion been caused by a malignant tumour formed at the bottom of the orbit, the blow upon the eye, instead of being followed by a removal of the preëxisting deformity, would, on the contrary, have been more likely to be followed by an augmentation of the mischief, if not the rapid destruction of the eye. The protrusion of the eye has now nearly disappeared; the strabismus, however, still continues, and vision remains extinct. —*Transactions of the Philadelphia College of Physicians.*

#### USE OF GLYCERINE IN THE TREATMENT OF CERTAIN FORMS OF DEAFNESS.

By THOMAS WAKLEY, F.R.C.S. Eng.,  
Surgeon to the Royal Free Hospital, London.

THE class of cases to which I would draw attention in this report, are those of *cuticular* or *epithelial thickening* of the meatus, either *partial*, affecting the membrane of the tympanum, or *complete*, being continued over the entire auditory cul de sac. There is a greater or less degree of deafness, corresponding with the amount of thickening; cessation of the secretion of cerumen; frequently tinnitus, or a "singing and hissing sensation" in the ears, and tickling irritation of the meatus. The causes are, constitutional predisposition, advanced age, chronic inflammation, long-continued discharge following eruptive fevers and the applications of escharotics and irritants. Amongst the latter, I would mention oily preparations, the globules of which adhere to the sides of the meatus or membrana tympani, and become rancid, thus producing a very frequent cause of inflammation. Upon examination of the affected ear, we find the meatus shining and inelastic, of a pearly whiteness, the membrana tympani either clouded or streaked, sometimes having small elevations upon it. The meatus is quite dry, the cerumenous glands being choked up by the epithelial growth.

The mode of application of the glycerine, when treating this state of the ear, is as follows:—The meatus is well cleansed with tepid water and then dried by means of the forceps and cotton. Glycerine is now poured into the meatus, and a plug of gutta percha, softened in boiling water, made to fit the external opening; this takes the exact form of the ear, becomes hard, and effectually prevents either the entrance of atmospheric air or the exit of the glycerine. The ear should be examined daily and the same process repeated. The lining membrane can be examined with a blunt silver probe, passed gently through the speculum auris, to ascertain the effect of the glycerine upon the cuticular thickening. The meatus will gradually lose its shining pearly appearance, and softened pieces will fall off, and can be removed either by the forceps, or gentle syringing. The practitioner should never attempt to tear them away, but allow them to come away by the means just stated. The treatment occupies ordinarily from two to four weeks, and is generally without any pain or inconvenience of any kind to the patient, and the results, in some cases, have been very gratifying. In the after-treatment the patients are directed to moisten the auditory canal at least once a week with glycerine, applied by means of a camel hair brush; this will generally prevent a recurrence of the cuticular thickening.

The *modus operandi* is simple enough—the glycerine being kept continually in contact with the part, acts mechanically, either absorbing or penetrating the epithelial coating, and separating the individual particles.

With respect to the permanence of the relief—some cases always require the presence of glycerine as the best known substitute for the natural secretion of the aural membrane. The frequent introduction of the glycerine tends to restore the external meatus to a healthy condition, and fit it for the proper transmission of sound.

The mechanical power which glycerine possesses in separating this epithelial growth in some cases is very remark-

able. I was consulted about two months since by a lady of rank, a patient of Sir James Clark, for deafness in both ears. In the right ear there was almost total deafness, from an enormous amount of epithelial thickening, which narrowed the calibre of the auditory canal, so that it would not receive the smallest-sized speculum. The depth of the *cul de sac* was also much less than normal, from the same cause. The lady was between 70 and 80, and told me that she had been deaf from her childhood in that ear; and there is but little reason to doubt that the deposit had been accumulating and hardening during nearly the whole of her life. The glycerine was used in the manner already described, and its action was very beautifully illustrated. A short time since, a large mass of the softened growth was removed without any inconvenience to the patient,—a larger quantity, perhaps, than I had ever before separated from the ear. The calibre and depth of the ear will therefore be increased considerably when the swelling of the lining membrane shall have subsided from its having been saturated with glycerine; this will gradually exude and come away. This case is still under treatment, and I shall mention it again at a future period, when the effects of the treatment upon the hearing can be safely declared.

I may mention another case, in the family of a nobleman, patients of Sir B. Brodie, where very considerable thickening existed over the entire aural *cul de sac*, but which readily yielded to the softening action of the glycerine, although it had previously resisted the use of caustics and various applications of the essential oils, &c., ordinarily employed.

The following cases are examples of the action of the glycerine on this class of chronic diseases of the ear:—M. R——, a clergyman of Hants, aged 66, applied, June 16, 1851, suffering from deafness of the right ear, which had existed for more than twenty years; indeed that organ had become wholly useless. Upon examination, I found the meatus polished and dry, quite inelastic to the touch, and of a dull white colour. The central part of the membrana tympani presented even more opacity than the other parts, and no secretion could be detected in the ear. I applied the glycerine after having well cleansed the meatus, fitting the gutta percha plug after the manner already described. This treatment was repeated every morning, and at the end of fourteen days I was enabled to remove a large portion of pulpy epithelium. Again, four days afterwards, more softened skin was taken away. The ear was well syringed, and all the smaller particles removed. Upon examination of the ear with the speculum, the meatus was found much improved in appearance; the membrane slightly swollen, from saturation by the glycerine; there was still, however, a portion of the cuticular deposition hanging on the left side. Upon testing the patient's hearing with the sonometer, it was found to have improved two degrees. The same treatment was then continued, and at the end of a week the last piece came away. The ears were again gently syringed, but with no further effect. A small portion of wool was then placed on the external opening of the meatus, and the patient was directed to return to me in four days. Upon his visiting me as desired, his hearing was again tested by the sonometer, and it was found that he had improved six degrees. There is little doubt that the deafness in this case was owing to the mechanical obstruction in the passage of sound produced by the cuticular deposition. When I last heard from this gentleman, there had been no return of his deafness.

H. M——, a dissenting minister, aged 38, consulted me, August, 1851, for long-standing deafness of both ears, which he stated would ere long cause him to retire from his profession, as he could hardly hear his own voice. The meatus throughout had that "parchment appearance" so characteristic where cerumen has ceased to be secreted. The membrana tympani presented a similar appearance. The same treatment was resorted to as in the foregoing case, and the result was equally successful. In sixteen days two soft, pulpy, membranous pieces were removed, and in a month his hearing, on being tested by the sonometer, was found equal to the lowest tone but one of the

instrument. During the treatment it was found necessary to attend to the general health of this patient, and preparations of steel and the mineral acids were employed with great advantage. I am in correspondence with this patient, and he still retains his improved hearing. From the history he gave of his malady I consider that the thickening was caused by constitutional predisposition, or, as he termed it, a "deaf tamt" in his family, as several other members, both older and younger, were similarly affected.

H. T.—, consulted me at the Royal Free Hospital (by direction of Mr. Edwards of Brompton), November, 1851. He had been deaf twenty-six years, and presented, in every particular, a case of strongly-marked cuticular thickening. He stated that he had suffered from inflammation of the ear, experiencing, at the time, excruciating pain. This lasted for three or four months. He was told it was neuralgia. As the pain left him, the deafness gradually supervened, increasing daily. This case occasioned me much trouble, from the want of punctual attendance on the part of the patient; at length, however, a considerable mass of almost cartilaginous consistence came away from both ears, with very great relief to the patient's hearing. Caustics had been previously used for the cure of his deafness, to a very great extent; but as the man said, always making him worse instead of better, causing pain and inflammation of the ear.

This case, in its result, was one of the most successful that has fallen under my notice.

In this report I feel it absolutely necessary to caution the profession against the use of the impure glycerine in the market. Several samples have been forwarded to me by both surgeons and patients. Upon careful examination of the liquids, I found only one sample to consist of pure glycerine; the others had a low specific gravity, or contained a considerable quantity of lead or of rancid oil, having been manufactured from putrid fat.

Several letters have been sent to me on this subject; the following extract is taken from one that I received from Dr. Houseman, Newcastle-on-Tyne:—"The use of glycerine in certain forms of deafness is likely to suffer from the impure samples in the market: it would be well to remind the profession of this fact. Messrs. Gilpin, of this town, have supplied me with the preparation pure, and several patients have been cured by the application. Glycerine should be a clear, scentless syrup, intensely sweet, instead of the rancid stuff usually sold under that name," &c.

Thus it is easy to account for failures in many cases that have been reported; and I would strongly urge surgeons who are treating certain forms of deafness with glycerine to test it themselves, and thus be certain of the purity of their agent. Pure glycerine should be a white, syrupy fluid, inodorous, specific gravity not less than 1.32, quite free from oily globules and oxide of lead. The latter may be detected by passing through it a current of sulphuretted hydrogen, which will easily blacken it. Any fatty matter may be discovered by mixing it with water: the disagreeable smell will at once prove that it has been manufactured from putrid fat.

In conclusion, it may be said, that impure glycerine being so easy of detection, it is desirable that its utility as an agent in the treatment of deafness will not henceforth suffer from the employment of an article that has no nearer affinity to glycerine than the name.—*Lancet*.

**NASAL ARTICULATION IN CHILDREN.**—In the *Union Médicale* M. Trousseau speaks of an affection to which children are subject, which is principally characterised by a nasal intonation of the voice. The complaint frequently dates from an antecedent attack of angina, with difficulty of swallowing, and often leads, at first sight, to the suspicion of imperfection in the palate. The chief appearances found on inspecting the throat are patchy congestion of the pharynx, enlarged tonsils, and pendulous uvula, which latter the author believed to be due to a species of paralysis. His treatment consists in the topical application of the nitrate of silver.—*Prov. Jour.*

## INFANTILE PHLEBITIS FROM INFLAMMATION OF THE UMBILICAL VEIN.

By W. HERAPATH, M.D., M.R.C.S., Bristol.

**HISTORY.**—Mrs. Jotcham was confined by me on the 24th of February, 1852, with her first child, a fine, healthy male. The labour was comparatively an easy one; everything proceeded perfectly satisfactorily until the sixth day after delivery. A slight hæmorrhage took place from the umbilicus at the period of the separation of the shrivelled remains of the funis, but this would not have been considered worthy of remark, had not other important symptoms subsequently developed themselves.

March 3rd. Some signs of uneasiness; griping and gastric disturbance appeared: the evacuations were scanty and unnatural, consisting chiefly of curdled milk. Vomiting was also present. Castor oil was ordered. 4th. The child improved under the treatment. 6th. As the above-named symptoms reappeared, the oil was again ordered; and as constipation existed, a larger dose was used and again repeated. A carminative was also prescribed, to expel flatulence from the stomach. 7th. The evacuations very scanty, deficient in bile, and chiefly consisted of curdled milk. The two doses of oil had only produced one movement. I ordered one grain of calomel and four of rhubarb; and directed them to be repeated in the morning, if necessary. 8th. Both powders were given, and some evacuations, having a more healthy appearance, resulted. The infant was considerably better. There were occasional spasmodic pains, accompanied by retraction of the limbs: slight shivering and moaning also occurred occasionally. The child was far from easy, but I did not see much to excite alarm. 10th. The nurse called on me to say that the child had become much worse, and "that it appeared swollen all over." Upon visiting it, I found that erysipelas had developed itself upon the index finger of the right hand, and also in the corresponding finger on the opposite side. A slight blush of erysipelas also appeared upon the second toe of the right foot: the knee was tumid, tender, and hot, but not erysipelatic. The little infant appeared to be in considerable pain; was almost constantly crying or moaning; vomiting often, with frequent hiccough: it was feverish, refused the breast, and scarcely slept at all. The bowels were somewhat tumid, and presented a general tympanitic appearance. The umbilicus was perfectly sound and healthy: there was no hernia. I ordered an evaporating spirit lotion to be constantly applied to the inflamed and erysipelatous spots, and another dose of castor oil to be administered.

The occurrence of erysipelas in this case was entirely without any apparent exciting cause, and at first was inexplicable. The mother was in good health; the apartment was free from currents of air—in fact warm, without being destitute of ventilation; the child had never been removed from it, and it had been carefully and attentively nursed. The appearance, however, of erysipelas, in some measure accounted for the other anomalous symptoms.

11th. The child was decidedly worse. The erysipelas extended upwards to the elbow on the left side; the fingers were considerably enlarged, and very red; there was a puffy swelling just about the right sterno-cleido-mastoid, very tender to the touch; icterus plainly exhibited itself, the conjunctivæ were orange yellow, and the skin, where free from the erysipelatic blush, was generally yellow. This was not the case yesterday, but it came on during the night: the respiration was peculiarly hurried, short, and sometimes irregular, and sighing, but there were no cough or bronchitic râle; the pulse was rapid, fluttering, and weak; slight evidence of fluctuation was observed on the right finger.

In pondering over this strange combination of symptoms, the peculiar character of the erysipelas struck me: the rapid scattering of the disease—in fact, the coexistence of the erysipelas at various points of the system, appeared very marked; it had not that erratic disposition which that disease usually assumes. These, together with the manifest existence of pus about the finger-joints, led me

to imagine the entrance of pus into the system, whilst the presence of jaundice appeared to point to the liver as the chief part implicated; and it occurred to me that there was a general cause acting on the whole system, and I gradually came to the conclusion that phlebitis of the umbilical vein had produced a purulent fluid, which, entering the circulation, caused the peculiar combination of symptoms which rendered the case so interesting. I at once expressed my opinion to the parents and nurse, as to the nature of the case, as well as my conviction that the little patient would not survive; but in order to make an attempt to save it, iodine was applied freely over all the erysipelatous points. The lotion was ordered to be continued constantly; and a few grains of gray powder were prescribed, together with an anodyne carminative mixture, to be frequently administered in small doses.

12th. At two p.m., the patient was evidently much worse, and was sinking rapidly. The erysipelatous redness had disappeared, giving place to a dingy purple, or livid colour. The icterus had increased in intensity: the temperature of the surface had much decreased, and the extremities were cold; respiration was becoming embarrassed, very irregular, gasping, and accompanied by a mucous rattle, whilst the mental faculties were wrapped up in a decided coma, and the eyes were glazed and open. Occasionally the child would partially arouse itself and moan piteously, but it was not sensible to external impressions of light or sound. The hiccup had become very frequent; and the pulse scarcely perceptible from its debility, and also very rapid. Occasionally the colour of the infant would undergo a considerable change, the countenance becoming suffused with a livid purple, around the eyes and mouth being of a deeper tint. These symptoms gradually increased in severity, the respiration becoming still more embarrassed, and at length about eight p.m. it expired, in slight convulsions. Having represented the extraordinary nature of the case to the parents, they kindly consented to a post-mortem examination, at which my friend Mr. Parsons (to whom I had stated the nature of the diagnosis formed) was present.

*Post-mortem Examination.*—The whole surface of the body was of a deep orange yellow colour; also the conjunctivæ. Collections of pus existed at all the erysipelatous points: about three drachms escaped upon making a puncture with a scalpel upon the inside of the right knee. At the second joint of the left index finger a similar puncture was also made, and a teaspoonful of thick yellow pus escaped. It was beneath the integuments only, and not in the joints, in either case. About two or three drops issued upon incising the toes, in the same way. Upon cutting through the integuments at the usual position for examination, a purulent deposit was opened at the clavicular articulation on the right side. This was superficial, being situated beneath the layers of fascia underneath the platysma myoides, and between the sternal and clavicular attachments of the sterno-cleido-mastoid. It did not appear to be in any distinct sac, but below it was bounded by the junction of the fascia to the clavicle; above, the probe would pass easily in the direction of the muscle, and pus had evidently taken the same course. About two drachms of pus were found in this situation. The umbilicus was perfect, and the cicatrix sound; the umbilical vein was large, and rounded. Upon cutting it across, within the integuments, it was found to be pervious through its whole length, and filled with a curdy purulent fluid, which became more purulent as the vein was traced backwards to the liver. There were not any purulent deposits in this viscus, but it was everywhere congested and of an uniform colour. The gall-bladder contained merely a few drachms of transparent, colourless, viscid mucus; its duct appeared impervious from some cause. Upon tracing the hepatic branches of the vena porta, they were found to contain pus, even to some of their smaller subdivisions, both in the right and left lobes. These appearances, however, were not general. Two main branches and their ramusculi were principally thus diseased; one on the right, and the other on the left. The greatest portion of the pus

had found its way to the right auricle through the vena cava ascendens, which of course is but a continuation of the trunk of the umbilical vein. Some slight coagula were found in the auricle and ventricle. The pulmonary artery was obstructed by tolerably firm coagula. The lungs were carnified, but of a more florid colour than from hepatisation, and appeared to resemble the lungs of an infant still-born. The inferior lobes, as well as one of the superior, were solid and did not crepitate; the other lobes were crepitant, but congested; no purulent deposits, however, were found, although carefully sought for. The foramen ovale was still pervious, although it had progressed towards obliteration. The opening was bounded by two curved margins, the superior being more deeply curved than the inferior; the long diameter was antero-posterior, taking the usual position of the heart into consideration, and measured one-fifth of an inch. The supero-inferior diameter was one-seventh of an inch. The ductus arteriosus was impervious, but the obstacle to the passage of a probe through it was very slight indeed, and it was contracted and indurated. The left cavities of the heart contained some coagula, dark in colour, and rather firm and stringy. The thymus was not of unusual size, or otherwise abnormal.

*Remarks.*—The post-mortem fully bore out the diagnosis made during the life of the little patient, in every respect, as far as the nature and cause of the disease were concerned; but I had certainly expected to find extensive purulent deposits in the liver and lungs. These organs, it is true, exhibited the early signs of purulent absorption, but they had evidently suffered less from the pyæmia than usual. The current of purulent blood had found its way to the right auricle through the vena cava, without much troubling the hepatic circulation. It had here split into two portions; one, the minor, going to the lungs, and inducing solidification; the other, and greater, passing through the foramen ovale to the left auricle and ventricle to the aorta, whence it proceeded through the systemic circulation and produced the local deposits found in the capillaries of the extremities, &c. The open condition of the foramen was not speculated upon, and overlooked until found at the post-mortem examination; but when discovered, it at once cleared up all difficulties. Had this aperture been closed, the intensity of the disease would have been shown in the lungs and liver without doubt; in the former principally, as the pus would have followed the course of the circulation: the liver also would have suffered, but in a minor degree, inasmuch as after birth the umbilical vein does not carry any blood into the vena porta.

In this instance, the phlebitis appeared to have crept along the lining membrane of the veins to some of the ramifications of the vena porta, and to have generated pus in its progress. These globules were then washed by the current of blood into the hepatic portal capillaries; and they would have induced deposits, had the infant lived a few days longer to give time for the development of pus, according to the physiological laws of its genesis, from the multiplication of its nuclei and nucleoli.

The umbilical vein was brought home, and its contents submitted to microscopical examination. Pus globules were detected, and the existence of softened fibrin was also recognized by the action of reagents.—*Lond. Jour. of Med.*

#### NIGHTMARE CAUSED BY ELONGATION OF THE UVULA, AND CURED BY THE ASTRINGENTS GIVEN DURING AN ATTACK OF CHOLERA.

By J. H. RAUCH, M.D., of Burlington, Iowa.

Mr. — is a young lawyer, with whom I became acquainted in May, 1850. He was of a pale and feeble aspect, and extremely nervous, the sight of blood causing him to faint, as also disagreeable thoughts and objects; he in one instance swooned while sitting in a room where the operation for cataract was being performed, he not seeing the operation. He occupied a room on the same floor of the hotel with me, and I had frequent opportunities of seeing and speaking with him. I soon perceived that previous to speaking or swallowing, a peculiar spasmodic action took

place, as if he had to remove something from his throat; this done, he could speak and swallow freely. He was extremely sensitive, now cheerful, then depressed. For the last three or four years, he suffered almost nightly from the nightmare, and at that time the recurrence of the attack was more frequent and increasing, he often having it three or four times during a night, making sleep any thing but pleasant and refreshing to him. His sufferings can be better imagined than described; they affected his general health, and exercised a very depressing influence upon his nervous system, so much so that I thought of advising him to return to the east, to spend the remainder of life with his friends. He dreaded the approach of night, and made it the particular business of his friends, who roomed near him, to awaken him should they retire after he did. One day while witnessing the effort he made, previous to his being able to speak, I asked him to look at his throat, to which he readily acceded; and upon examination, found his tonsils slightly and his uvula greatly enlarged. I was immediately satisfied that the elongation of the uvula was the cause of the difficulty he was labouring under when first attempting to speak or swallow; not thinking, however, that it also was the cause of the nightmare. In the early part of the month of August, he had an attack of cholera. He suffered much from prostration and heat, but more so from the feeling of faintness and suffocation that harassed him constantly; so agonizing was it, that upon several occasions he thought he was dying. As the cholera symptoms improved, the nightmare disappeared, and since then he has had but two slight attacks, and these were directly traced to having a sore throat. His health is good, he looks well, and is heavier now than he ever was before, and his uvula is not half as large as before the attack of cholera. While suffering from an attack of nightmare, he has often described his feelings as being almost intolerable, and breathing next to an impossibility. He had no power to move or speak, and the only effort he could make to arouse himself was that of loud and heavy breathing, and the exertions he made to throw off the incubus increased it. After he got over the nightmare, which, though it might last but a few minutes, seemed to him an hour, he would be pale and exhausted, and in a profuse perspiration. During this time he was fully conscious of where he was, and what was going on around him. I am convinced he was cured by the astringents administered during the attack of cholera.—*Amer. Jr.*

#### NEW MODE OF REDUCING STRANGULATED HERNIA.

By Dr. T. A. WISE, late Surgeon H.E.I.C. Service.

THE following are the particulars I promised to send you, regarding a new method of reducing strangulated hernia. While I had charge of an hospital in India, an elderly man was brought to it with a strangulated inguinal hernia. After in vain employing the usual means of reduction, I was preparing to liberate the gut with the knife, when a Mussalman gentleman suggested, that the following method should be first tried, as he had seen it successful. As it appeared most simple and effective, I at once proceeded to try it. The patient was placed upon a table, and a long sheet, folded several times on itself, was carried round the lower part of the abdomen of the patient, was twisted on itself in front, and again on the sides, so as to enable an assistant, standing on each side of the patient, to hold the extremities of the sheet, and to pull them gently upwards, or towards the patient's head, while a third assistant held the feet steady, and the surgeon used the taxis. As the gut immediately above the strangulated portion was superficial and distended with air and liquid, it was drawn upwards with considerable force from the hernial sac, which was assisted by the surgeon using the taxis; when the strangulated portion was immediately reduced. This simple method may, in a very large proportion of cases, be employed with perfect safety and at an early period, before inflammation and thickening has complicated and increased so much the danger of the operation, which is thus rendered unnecessary.—*Ed. Monthly Jour.*

#### TREATMENT OF ULCERS BY THE EXCLUSION OF ATMOSPHERIC AIR.

By Mr. HOLT of the Westminster Hospital.

Case 1.—Henry H—, aged 38, was admitted, under the care of Mr. Holt, January 13, 1852. The patient is a carpenter, and states that five years before his admission an ulcer formed by the side of his left tibia after a very severe attack of rheumatism. He tried to heal it by various means, but did not succeed, and about one year before his reception into this institution he went to the Middlesex Hospital, with an ulcer of the size of the hand, and one eighth of an inch deep. By lotions of sulphate of copper, rest, and a roller, the sore was reduced to the size of a sixpenny-piece. He was discharged, and went to work, and in the space of three or four days the ulcer had again reached its original size. He treated himself for a little while, but soon applied at this hospital, where the sore was first poulticed for three or four days. When the inflammation had been subdued the ulcer was dressed in the following way:—From a piece of adhesive plaster, somewhat larger than the sore, a portion, just the size of the latter, is cut out; the plaster is then applied to the part, and painted with collodion. Oiled silk is now placed over the ulcer, and made to adhere to the plaster by means of the collodion, by which process the air is completely excluded from the ulcerated surface. The whole is then secured by strips of adhesive plaster placed crosswise, and by a roller running from the toes to above the knee.

This dressing used to be left undisturbed for a week or ten days, and by being taken off with care did not give the least pain. The patient remained in the meanwhile mostly in bed, and had good diet. On the 23rd of March, about nine weeks after admission, the sore was completely healed, but by walking up and down stairs it re-opened to the size of a fourpenny-piece. The same kind of dressing was continued, and in a fortnight the patient was discharged, the ulcer being quite cicatrized.

Case 2.—Richard C—, a labourer, aged 40, was admitted March 12, 1852, under the care of Mr. Holt. The patient had been run over the loins by a cart, and had escaped without much injury. Whilst under treatment he complained of an old ulcer on his right leg, about the size of the palm of the hand. Poultices were applied for a few days to subdue inflammation, and the same kind of dressing as described above, was employed. This patient, however, was allowed to leave his bed, and walk about the ward. In the space of three weeks the sore was healed, and the man has been discharged.—*Lancet.*

#### REVIEWS AND NOTICES OF BOOKS.

ON FATTY DEGENERATION OF THE PLACENTA, and the Influence of this Disease in producing Abortion, Death of the Fœtus, Hæmorrhage, and Premature Labour. By ROBERT BARNES, M.D., &c. 8vo. pp. 22. London. 1852. (From Volume xxxiv. of *Medico-Chirurgical Transactions*.)

TILL within the last few years the pathology of the placenta was, we may almost say, wholly unknown. In fact, until the publication of Dr. Simpson's paper in the forty-fifth volume of the *Edinburgh Medical and Surgical Journal*, there was no British pathologist or accoucheur who had investigated this subject. Isolated cases of extraordinary morbid appearances in this organ were occasionally noticed by authors, but in a very loose, superficial manner. Even the excellent essay of Dr. Simpson confines itself to the examination merely of congestion and inflammation of the placenta. It seemed as if accoucheurs thought this organ unworthy of their attention, because of its short continuance in the animal economy. And yet, if we consider the importance of its functions—brief though they be—that upon its integrity depends the welfare, and, in a certain degree, the life of two beings, we feel bound to say that this total neglect of its pathology was most unaccountable.

In the pamphlet now before us, Dr. Barnes has contri-

buted some very valuable observations on a serious form of disease to which the placenta is liable—namely, fatty degeneration. This, according to his description—and our own experience agrees thereto—generally affects the maternal surface, which is found studded with fatty masses, varying in size according as the disease is more or less advanced. One effect produced by this partial deposition of fat is the loss of homogeneity in the placental tissue, so that the organ is no longer in a condition to follow the movements of the uterus, and preserve its connexions. Its presence, moreover, tends to obliterate the cavernous structure, and destroy the utero-placental vessels. A frequent consequence of these morbid changes is (the author informs us), partial separation of the placenta from the wall of the uterus, thus giving rise to hæmorrhage, and probably premature labour. If this fatty degeneration proceed far without inducing labour, we can readily understand, as pointed out by Dr. Barnes, that a period will arrive when the fœtus must perish from insufficient aëration of its blood. Dr. Barnes describes three stages or degrees of this disease, entailing different consequences to mother and child:—

“In the first kind, the disease has made so little advance that the child may be carried in safety to the end of the natural term of gestation; in the second kind, of which I have given two examples, the disease has proceeded at such a rate as not necessarily to involve the destruction of the child. At the seventh month the child is viable, and if, as I have shown, premature labour should by any means be induced before the child has perished, a living child may be born. I have now to indicate a third kind or degree, which not only places the mother in danger, but necessarily destroys the embryo. If the disease proceed so rapidly as to have invaded a large portion of the placenta in the early months of pregnancy, it may be the immediate cause of abortion.” (p. 14.)

For a description of the minute pathological changes produced in the placenta by this disease, Dr. Barnes is indebted to Dr. Hassall, whose microscopic report upon this subject is embodied in the paper, and in itself possesses much interest and value. In thus noticing the *brochure* of Dr. Barnes, which we do with much pleasure and satisfaction, it must be confessed our chief object has been to draw the attention of accoucheurs to the importance of minutely examining the condition of the ovum, and especially the afterbirth, in all cases of abortion, hæmorrhage, premature labour, death of the fœtus, and morbidly adherent placenta. Our knowledge even of the morbid anatomy of this organ is as yet very incomplete, and of its pathology still more so; but the important position which the placenta holds in relation to the mother and child, supplies the strongest reason why we should endeavour to make ourselves acquainted with the morbid lesions to which it is subject.

#### CONFESSION OF A DRUNKARD.

I was born in 1800. My father was an honest and an upright man, but he was much afraid some misfortune would occur to me, and his words have proved true, for I have gone through more than all my sisters and brothers put together; but I have earned the most money. With all my earnings I am now by far the worst off; all my sisters and brothers are in very creditable circumstances, while I am now within a prison wall. My father left seven children. We were all sent to live with my grandmother, but we were all soon separated. I was put to live with a man at the place where I was born. He was a man that I believe never attended any place of worship, except upon the occasion of a wedding or burying; but I often heard him and his mates boasting which had the best game cock, and which was the best fighter. He had eight brothers, who were all fighting men: they were all hand-loom weavers, and they kept a snug farm. It was about the time that peace was made, after the battle of Waterloo.

At the beginning of the week, for two or three days, it was drinking, fighting, and cock-fighting, card-playing, &c. His wife died, and we were then removed to his parents. We were about twenty, all in one family. There I learned to know what it was to be without parents, for I was under the control of the whole family: if I disobeyed any of them

I was rewarded with a kick or a blow. One Sunday I went to see my grandmother, and I had four or five cuts on my forehead and ears, some of them bleeding at the time; so my grandmother got me into the factory, Lower Darwen, where I was bound apprentice for seven years. I never was so happy as I was at that time, though I never saw anything like religion exercised. The master was not content with the bell-ringing, but used to come to every door in the morning to call his workpeople up; and I have known us to work until sometimes eleven o'clock at night, and on Saturday nights occasionally until twelve; and after that time he would take all the men to the public-house, and give them plenty of drink, and they would continue drinking until the morning. On the Sabbath they would lie in bed all day.

I served my time honestly, and I had not a bad master after all; but he was a heavy drinker. In his mill a school-master attended twice every day, to teach all the hands that had a mind, and from him I got most of the little learning I am possessed of.

I was married August, 1824. We had £33 and a few shillings, and all things went on very smoothly for a long time. I still kept in work at the same mill, and we got on very well until the mob attacked it in 1826, and broke all the power-looms. I was six months without work, so I went over to Wigan, and had 10s. a week for looking over the other spinners, and was getting upwards of £2 per week off my own wheels, and all this time never got to drinking; but soon after got to like drink, and made a practice of going every Saturday night with my wife and the other spinners, till at last I got to taking whole days. When I first started to drink, I had above £200 in money, and as good furniture as any working man need have. We had been married above nine years before I began resorting to these places, which have been my destruction. I was a happy man. I used to have my children well clad, well fed, clean, and comfortable, and my wife the same; and I could go to a place of worship on a Sunday. When the labour at the factory was over, I used to work two or three hours at home for my own pleasure and advantage. I had a lathe, and got many a crown for making chairs, &c. I carried on drinking for a long time, still going longer and worse, until my money began to lessen very fast; so I began to be more steady, and did not drink much for near twelve months. I earned that time, with what I got in the factory, upwards of £3 every week; so in one year I saved between £70 and £80, besides maintaining a wife and four children. When I think on those days, and my being now confined in a prison, and that same wife likewise, and one of those dear children that we used to take such delight in, confined within a few yards of me! And what can be the cause of this, do you think, seeing that my former circumstances were so prosperous? I can explain the cause in a very few words—neglect of the Sabbath, drunkenness, and bad company; but drunkenness, I do affirm most solemnly, has been the cause of all the other evils. But to my story. I worked at that mill twelve years, until our master's health began to decline, and the mill began to make short time; and what little the mill did run I was not to be found, for my time was the most employed in the public-house; and this was the time I began to ruin myself; and still worse, my wife commenced drinking, and then all soon went to ruin. At our master's death the mill stopped altogether, after which I left Wigan. I had been at Bolton, and taken a beer-house, and had promise of work at Mr. Bolling's. I took the beer-house, thinking as my father and mother-in-law had nothing to do, they might make a little by selling beer. We might have done very well had I been steady, for I got a very good pair of wheels, and the house I had taken was convenient to the factory, and we got a good deal of custom. They came at night when the factory was over, and we would let them stop until twelve or one o'clock in the morning, cursing and swearing, and me, and perhaps my wife and her father; and no one but the old woman to fill, and perhaps twenty men drinking in the house. I have slept in my clothes all night, and have had to go to the hot factory at half-past five in the morning, and the spinners, perhaps four or five, lying on the floor, they were so drunk. As soon as I could get them up to go to work, they wanted more drink; and we would sometimes take five or six quarts to the factory; and as soon as we could we would get all our big piecers to spinning, and we would creep out of sight of the overlooker to drink, so that at breakfast time we might have another fetching; and this was the way we used to go on, so I got the name of a regular drunkard; and the manager told me if I did not give up the beer-shop he should be obliged to acquaint the master, for he said all the spinners

were getting drunkards. At this time my wages, on an average, after paying for rent, milk, and beef, was about 32s. per week clear; but I found that the hot factory and so much drink was causing my health to decline; so I left Bolton, and went to spin for Mr. Sidebottom, in Derbyshire, and the old people came to live with me, and we were very comfortable. I was getting much less money than at Bolton; but we began to mend; for I began to joiner a little at night, and it was well I did so, as the mill went on short time for above six months; and as there was no one who kept a joiner's shop, I got as much work as I could do. Just at that time my wife fell sick, and continued so above twelve months; and then one of the children died. I took much to drinking through the death of that boy; but drinking was a sinful folly, and if I had the same to do now, I think that instead of flying to the alehouse, I should fly to the house of God. At this time I was getting but small wages comparatively—about £1 2s. or 3s. per week, and my three children used to get about 10s. per week between them. I was there about nine months weaving, before I got a situation as overlooker. I was at that place but a very short time before my mother-in-law died; and that was the worst shock I had ever experienced, for we had six children, and my wife was not able to attend to them on account of losing the use of one hand during her sickness. I think after the death of my mother-in-law I was more negligent in my duty to my family than I was before; and I began to drink and neglect my work; sometimes off my work a week or a fortnight drinking; and the last time I was off, the master told the manager I must not start any more. With that I took about £2 and went to Ashton to see for work; but instead of looking, I went straight to the place of drunkenness, where I knew I should find plenty of company that were spending their money and neglecting their families like myself. I could at that time have gotten near £2 per week with comfort, if I had been a steady, sober man. I went to Ashton on the Wednesday, did not return home until Sunday morning, with not one penny in my pocket, and £1 in debt. I went to Blackburn to see if I could get work, but when I got amongst my old friends, I could find but little time to look after employment for drinking. I was three weeks at Darwen and Blackburn, and had come near forty miles for work, but did not ask any person for work, though I had it offered me if I would bring my family. At last I did, and we were getting on very well, but my wife took to drinking very heavy; she had got acquainted with a class of women that made a constant practice of drinking. Often when we came from the mill have we found her drunk in bed, and nothing prepared for us to eat, and having at that time four children unfit for work, who were destroying and wasting the provisions we had to live on, for the want of a mother to look after them. Bad as I was, I never lifted my hand to strike her in all my life, for I was aware that if I had been a sober man, my wife would never have been a drunkard; so I began to think it would be the best plan to leave the town altogether, to separate my wife from her drunken companions; so we went to Bolton, and I made the acquaintance of a regular set of drunkards, who would do almost anything to obtain money to spend in drink. I was always ready for a spree, and they were never short of money, though they were scarcely ever seen to work. One of them was a very good shoemaker; his name was N. S.; the other was a labourer, and went by two or three different names. One day, as they were all drinking at my house upon a Sunday, I said to them, "I do not know how you men scheme it, for you are never without money, and you work very little." "Ah!" said one of my new pals, "there is none who will work except fools and horses." I said I should be very glad if they would teach me, for I was getting very tired of working; and they did learn me, to my sorrow. A very short time after they told me the grand secret, that they got their living by making and paying bad money; and they told me they could get as much money on a Saturday night, as I could get in a whole week by working. So it was agreed they should get some ready by next Saturday, so we all three set off to Tyldesley Banks. We went through Straight Gate, and came back through Chowbent, and we paid that afternoon and night about £4. They declared I was one of the best payers they ever saw; and no doubt I did my part well, for they gave me drink, and drink possesses me of a false spirit. They gave me 10s. for my share in that afternoon's work, and 10s. in bad money; and I paid that 10s. on Sunday in good time; but when they got to know I paid it in Bolton, they said I must not pay any more, for it was very bad to pay in the town we reside in, for it may cause suspicion, and that

sometimes caused inspection. I kept company with those men upwards of twelve months, making and paying more or less every week. I had left off work long before the year end, and followed nothing except the bad money trade and drinking. But I had many narrow escapes from the police. They were both taken before me. While we were all drinking in a liquor-vault in Bolton, in came three policemen, and took both of them, but they took no notice of me; so I went home as soon as I could, and removed all that was in my house out of the way, for I had about £4 or £5 of bad money there at the time, and three moulds. They were both committed to Kirkdale for the assizes. At their trial, I provided them both with counsel, and they both got acquitted. When they came back they soon commenced their old trade again, and wished me to join them; but for three or four months I had nothing to do with them as regarded the bad money, although I went with them drinking, until at last I joined them at the same game again, and I was not long with them the second time before I was taken prisoner. I got with my old mates again, and I asked them what I must give them to make me a few pounds, and they said they would make me £10 for 10s., if I would find the metal, and they would come to my house to make it on Sunday morning; Sunday was the best day for making, as the police were always engaged in other business; and I was to buy a dozen of Dixon's best Britannia metal spoons. We all got quite drunk that night before we parted, and it was the last time we three got drunk together, for in a few weeks we were all three in prison, myself first. I was taken in Bolton, in a drunken state, with about thirty base sixpences, shillings, and half-crown in my possession, for which I got twelve months. When I had served my twelve months, I found my wife and the younger children in the workhouse; those that were old enough to get their own living had left her, so when I came out I had no home or friend to go to, for all my relations had turned against me; so I went to Bolton, and was well received by N. and a few more of the same sort; there was plenty of drink, and plenty of bad money. On Monday morning my wife got a pound from the overseer to leave the workhouse, with which we bought furniture, and I got work for myself and as many of my family as were able to work. We had not been above ten days in work, before the police came to the factory and told the master we were a set of bad money makers; so the master sent for me and told me we must get another situation, as we had been very badly reported to him, so we were all without work again. So I asked myself what must be done now, it will be of no use my trying to get work in this country; so I said to my wife "Go and get the children in work if you can, and I will try the bad money system again, in order to get a little to leave the country altogether, if I can." Trade was very bad at that time, and we could get no work, so we continued paying until my wife was taken with Mrs. Preston. They both pleaded guilty, and Mrs. Preston got six months in Preston house of correction, and my wife three months. So I was left with eight children for that time, five of whom were not able to work, had there been any for them; but there was no work at that time for one-third of the people in Lancashire, as almost all the factories were either standing or running short time. So I went to the relieving officer and before the board of guardians; but the workhouse was full, so they gave me a paper to get soup and bread, and I was very thankful for it; but all we got from the charity was not sufficient for my family, for we were nine in all; how were we to live? To carry on with bad money was very dangerous, and owing to my wife being taken, the police came several times to my house to search, so I got a few shillings from the relieving officer to begin barbering; but I got very little custom, so I was determined to see my children starving no longer, for we were whole days and never tasted food, so I went to Bolton to see if my old mate N. S. could do anything for me. When I got to Bolton, N. had got twelve months in the New Bailey Prison, Manchester, for buying stolen goods, but his wife was very glad to see me, and gave me 5s., and put me about 5s. or 6s. worth of food up to take to my family, and she said she could let me have some metal that N. left. It had been stolen, she thought, for N. had told her she must keep it in the house. So as I was waiting of this woman raising the plant, I went to see my acquaintance old J. O. and K., as they had a quantity of base coin in plant, and they said if I dare pay any, I must have a few half-crowns or shillings; so I took a few of each sort. O. said if I had a mind he would come to Blackburn with me and stay with me until my wife came home, for no one knew him in that quarter. So I was glad of his proposals, and we returned together to Blackburn, having got

the metal from N.'s wife, and about six pounds in base coin. When I got home my eldest daughter was waiting up for me, so I went and fetched a gallon of the best beer and a pint of rum. Honesty is the best policy. Yes; for whosoever defraudeth his neighbour shall be found out, as my present situation in prison plainly shows; my wife is in prison, and my oldest son also. I am the father of nine children, or was so when I came here, but up to the time I write this I have heard nothing of them; we have had thirteen children; I am upwards of fifty years of age, and my constitution much injured by imprisonment; we have completely lost our character; had I done what was right in the sight of God and man, my children might have proved a blessing to me and my wife in our old age; and I am convinced had I done as I should have done, that one or two of those children now in their graves would now have been living, for my wife, through having to look after me, and being in trouble, neglected the little ones. It is my sincere wish, as a penitent, that those who read this narrative may profit by it, and I wish the reader to compare the commencement of my married life, when I never frequented the public-house, and was happy in my own house, with the amusement of joining or birdcage making, with that which followed. The publicans got so little of my money that we had always credit sufficient, and no person had to say, if they came to see us, we were short of anything. There could not be a more happy couple than we were; we never had a cross word for years after our marriage, and as to blows, I never struck my wife in all my life. Ah, but since I had to do with that destructive and ruinous drink and base coin, I have been the most unhappy man living.—*Winslow's Psychological Journal.*

DUBLIN: WEDNESDAY, MAY 26, 1852.

### MEDICAL REPRESENTATION IN PARLIAMENT

SOME new light appears to have broken in upon the minds of persons engaged in the consideration of our representative system with a view to its amendment: some glimmering of reason as to the justice of conferring the right to vote for members of Parliament on some other grounds than the payment of rent or poor rates. It seems at length to have entered into the contemplation of politicians to permit the interests of science to have their weight as well as those of trade, and to allow the lights from this source to illuminate legislation as freely as those emanating from less brilliant sources: in other words, an opinion begins to prevail that men may with safety be permitted to enjoy the elective franchise on the strength of a diploma or degree, or of any other proof of proficiency in arts or sciences. There is, it is true, nothing new in the conception; for the Universities of Oxford, Cambridge, and Dublin have long since had the privilege conceded to them, but the idea of a more extended application of the principle seems to have been reserved for later consideration. That such a view should be at length entertained does not surprise us, the foundation of it being so evident; and we are convinced that it requires nothing but the support of those interested in its adoption to secure its recognition. For the life of us we cannot see why these Universities should be represented in Parliament, while the Colleges of Surgeons of England and Ireland, counting their members by thousands, should remain unrepresented. It is clear that the practical results of a system are, in a practical point of view, of more importance than the pre-

liminaries which have led to them. That a professional man should enjoy the elective franchise in right of his diploma seems scarcely to admit of question; but that he should choose a special representative of his peculiar department may perhaps be denied. Yet it seems much more reasonable to provide such a resource for the protection of a body united by common interests, and having definite objects in view, than conceding it to such an heterogeneous mass as a university constituency. People will say that men are sent to Parliament to consult on the affairs of the nation at large, and not on those of particular bodies; but we all know that this is but the theory of the thing. The true state of the case is, that the representatives of particular interests go to Parliament to protect those interests, and to show how that protection is necessary as regards the public welfare. We have the manufacturing, agricultural, monied, colonial, legal, clerical, and many other interests, well provided for; and it therefore seems very unfair to deny such an essential provision to the medical, numerous as its components are, and important as its objects must be considered. To the absence of such representation in the legislative body must be attributed not only the gross neglect of all matters connected with this department, but the mischievous interference with its legitimate duties which are sanctioned not only there but in every department of the public service. If the Surgeons of England and Ireland had active, intelligent, and independent members to represent them in the House of Commons, they would not have to complain of the inadequate remuneration for their services to which they have now to submit, nor the intrusion amongst them of unqualified pretenders; neither would they have to tolerate the patronage of quackery by the State for revenue sake, nor the connivance in an organized system of advertising which outrages public decency, and does more to sap the foundation of public morals than many practices against which special legislation has been directed. We copy the following, which, indeed, suggests these observations, in order to provoke discussion on the subject; not in any idle vein, but with a sincere conviction of the necessity for the measure we advocate. Let the institution in question pursue its course. Its success will promote the general interest and pave the way for more extensive application of the principle upon which it relies:—

The claim of the University of London to send representatives to parliament rests on the most unanswerable grounds. In the first place, then, the pledge of equality implies the right to parliamentary representation, which has been enjoyed by Oxford, Cambridge, and Dublin, since the time of James I. Every constitutional reason which justifies the exercise of that privilege by the older universities will apply with equal force to the university of the metropolis. The most remarkable difference in the cases of the older and the new universities consists in the essentially ecclesiastical character of the former. But surely it will not be contended that the parliamentary privilege is entrusted to them on account of their conformity with the State creed. It will not be contended that because the metropolitan university is based upon the principle of excluding religious tests, it is therefore unfit for parliamentary representation. . . . Would the university possess a sufficiently numerous constituency? Seven hundred is surely a very respectable number; and when we reflect that there is a reserve of more than seven hundred under-graduates, who recruit the ranks to the extent of about one hundred annually, no fear can be entertained that the university would ever fall so low as to be classed in the category of decayed boroughs, which still retain the franchise long after they have forfeited every title to the trust. When the University of Dublin was invested, in 1614, by James I., with the privilege of returning two members, we believe it counted but six electors. But such is the inherent vitality, such the self-perpetuating develop-

mental force of institutions which derive the elements of their own growth from popular sources, gathering a constantly accumulating power from the unflinching aspirations of the human mind after intellectual improvement, that the university constituency of the sister isle now approaches, if it does not exceed, two thousand electors. The anticipated progressive increase of the University of London must be immeasurably greater still. Its metropolitan position, its cosmopolitan sympathies extending to all the great educational institutions of the empire, its free and unrestricted principle, adopting every existing college, and ever stimulating the foundation of others, must rapidly create a body of electors imposing by their numbers as well as by their intelligence.

Were the two great measures of incorporation of the graduates and parliamentary representation conceded, it is impossible to doubt that before many years the influence of the constituency of the metropolitan university would rival that of the first in the kingdom. With regard to the question of numbers, it is also worthy of notice that nearly one-half of the graduates reside in or near the metropolis. To establish the claim, a precedent—that *ultima ratio* of lawyers—is at hand. When Trinity College, Dublin, was first admitted to the franchise, it returned two members to the Irish parliament. By the Act of Union in 1800, it was allowed to return one member only to the united parliament; and lastly, by the Irish Reform Bill in 1832, it was empowered to send two members. Thus we have, within the last twenty years, an example of parliament creating a university member. The opinion of the most eminent reformers is pointedly in favour of extending the application of the principle which dictated that measure. Lord John Russell has declared that in any extension of the franchise the claim of science and learning must be more extensively recognized. Sir James Graham, in a recent speech at Carlisle, having no doubt the University of London present to his mind, thus expressed his sentiments:—"In distributing the representative privilege, I should pay respect to numbers in some degree; but at the same time I do think that, with great advantage, the representative power might be conferred on parties possessing intelligence and science to an eminent degree who do not now return representatives." Such a claim, indeed, will be the most universally acquiesced in of any. It is preëminently the claim of fitness and responsibility. It is a claim which wealth and station cannot, and would not, contest; for a power wielded by intelligence and knowledge is the surest guarantee of order and good government. It is a claim that the middling and industrial classes would cheerfully recognize, for its recognition would open a new avenue to advancement and distinction for humble merit. It is a claim which conciliates every interest, binding together by the sacred fellowship of knowledge the extremes of society, awakening in all, by the eloquent voice of science, the purest feeling of brotherhood, and the deepest sense of mutual responsibility.

All the qualifications for the exercise of the parliamentary franchise which have been successively devised, have manifestly had for their object the testing the fitness of the electors. Acting on the conclusion, to a great extent true, that knowledge ensures wealth, so wealth enables its possessor to acquire knowledge, a property qualification has been the most easy and the most general expedient. But in those cases where knowledge is more unequivocally indicated, as by the possession of an academical degree, any other test is superfluous; and this our parliamentary history most emphatically attests. The representatives of every county and borough in England—that is, the representatives of landed property, of commerce, of industry—are required to produce evidence of being worth, in one case £300, in the other £600 a year. But the members for the Universities of Oxford, Cambridge, and Dublin, are exempted from this requirement, in honourable acknowledgment of the more satisfactory security they present as the chosen representatives of literature and science. But literature and science, which have contributed so greatly to our prosperity, and the lofty position of England among the nations of the earth, are yet but most inadequately represented. Hereditary rank, landed possessions, commercial influence, the industrial masses, mere money, monopolize the representative power. It is the palpable interest, the bounden duty of the educated classes, and of none more especially than of the medical profession, to promote to the utmost of their ability the extension of the suffrage to the metropolitan university—a university which is essentially their own—a university which has contributed so much to raise the character of medical education, and to advance the profession of medicine in the public esteem.—*Lancet*.

## THE PHARMACY QUESTION.

NOTHING more conclusively proves the importance of this question, not only to professional but public interests, than the frequent recurrence to the subject of the following extract, both in Parliament and public discussion. It is evident that the subject is one involving considerations of high interest, or we should not have this annual reference to it. Whatever may be the danger apprehended that the parties before us may, like the apothecaries heretofore, desert their legitimate pursuit, and "turn to doctoring," we cannot deny them our approbation. The efforts they make to place the department of trade to which they belong under proper regulation are most praiseworthy:—

Now, viewing that Latin is the language of the medical profession in this country, that the *Pharmacopœia* is in Latin, and that physicians and surgeons write their prescriptions in Latin, there can be no doubt but that a competent knowledge of that language is necessary for those who have to read prescriptions and compound the medicines prescribed, and who also have to refer constantly to the *Pharmacopœia* in preparing compounds to be kept in stock, and always in readiness. For the better and full understanding of their business, it is equally necessary that such persons should be well instructed in chemistry, botany, pharmacy, and materia medica. And now, with respect to the counter-practice of the chemist and druggist, about which Dr. Webster so loudly complains, that such a practice is carried on, to a limited extent, as incidental to the business of the chemist and druggist, cannot be doubted; but I question whether it is so dangerous to the public, or so injurious to the interests of the profession, as Dr. Webster seems to imagine. I am pretty sure that, on the contrary, it is a great convenience to the humbler classes, who cannot afford to call in a qualified practitioner upon every little alarm or derangement of health, occasioned perhaps by a change of weather or irregularity in eating or drinking, of a temporary nature, and easily corrected by a dose or two of simple medicine. I am equally certain that this counter-practice of the chemist relieves medical men of a great deal of profitless trouble; for though the class of patients who resort to it pay their threepence or sixpence to the chemist over the counter, they are but rarely in circumstances to pay a doctor's bill; and it would be grievous to the profession to see any of its members dragging such persons into the county courts for payment. Dr. Webster says that it is his firm conviction that, by the passing of this bill, "counter-practice will increase ten-fold," for the chemists and druggists will, as he imagines, hold up their flaring diplomas to decoy and cheat the public into the belief that they are perfectly qualified to cure disease. Now, this is all, to say the least of it, but assumption, partaking, truly, a good deal of morbid apprehension. I wonder at it; for Dr. Webster is one of the last men in the world that I could have imagined would have viewed the influences of an improved system of education upon such an intelligent class of men in so unfavourable a light. I entertain hopes of better results from the passing of the bill, for I foresee that instead of making knaves and impostors of the chemists and druggists, as Dr. Webster apprehends, it will elevate their position, and make their trade a scientific pursuit, as it already is in the hands of many very superior men amongst them. And more, it will secure to the public, at the humblest shop, accuracy and safety in the preparation of medicines, upon the efficacy of which life itself may be depending. Of domiciliary visits to patients by chemists to treat disease, I have no apprehension. Such a practice is known to be incompatible with success in the trade of the chemist and druggist, and, as is truly remarked by Dr. Webster, none of those who are prosperous in that business attempt it. Counter-practice is quite a different thing; it is but temporary, and never extends to the regular and continuous treatment of any disease involving danger to life or limb; and, upon reconsideration, I hope that Dr. Webster will see that it would be beneath the dignity of the profession to notice it with the hostility of the restrictive clause that he suggests. The Doctor points to the restriction upon the French pharmacians as a model for us to follow in restraining the chemist and druggist from carrying on counter-practice. But it should be recollected, that in France medical men are not allowed to supply medicines to their patients, nor to derive, directly or indirectly, any profit from the sale of the medi-

cines they prescribe. In conclusion, I would express a hope that the profession will allow the bill to progress through parliament without offering any opposition to its provisions that may be open to imputation as selfish or factious, for there is nothing in the measure that compromises in any way the interests of any class of medical practitioners.—*Dr. Dillon in Lancet.*

#### A SHABBY TRICK AND ITS CONSEQUENCES.

At the late assizes in a southern county, an action was tried to recover damages against the directors of a railway for severe injuries suffered by the plaintiff, owing to the negligence of the servants of the company. Amongst the witnesses examined were, necessarily, the medical attendants, who, previous to the trial, were asked the question whether a certain sum would be considered by them sufficient remuneration for their long-continued services in the case (which at one time was thought to be hopeless from the severity of the injury), they replied in the affirmative; and when under examination, *swore* to the amount to be paid them. The jury took all the circumstances into consideration, and awarded large damages, which included the payment to the professional men; the plaintiff received the money, and then *cut down the sum offered on his part to the surgeons* by no small figure. It is said one of the attendants has accepted the reduced fee, but the other very properly seeks, and is determined, to have the full amount; not so much for the money, as to show that he will not be a party to a precedent which, in future, may act injuriously on his brethren in the profession. He deserves great credit for his determination.

#### CORRESPONDENCE.

##### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Advertisements offer £500 to any one who will prove homœopathy true: this, of course, is a puff. Will any one offer £100 to show it is a fabrication and a lie? Your remarks about the booksellers are true to the letter. Well may Mr. Gladstone, Mr. Carlyle, and others deplore the state of the bookselling trade. Lord Campbell, however, has given the matter its *quietus*; and we may shortly expect honest reviews and notices of books coming from the great warehouses. In the medical publishing world, things are worse perhaps than in any other: a miserable cliquism, with its attendant dishonesty, governing everything, at least in London. What is the result? The medical journals here have lost all moral control over the correct men of the profession. Hence a feud in Edinburgh, or a piece of mouldy ophthalmic surgery and abuse of infirmaries from your side of the Channel, is a regular gendarm: quackery, in every form, deluging the town. The true and good men here are better known in Leipsic, or Vienna, or New York. The Owens, and Pagetts, and Marshall Halls, give up the thing in despair; while every kind of "juvenile depravity" in guise of book, if only inside the limits of a certain clique, is puffed to the skies. New and beautiful facts here lie open every day in the hospitals and college lectures, but they must get age like vinous fluids, and go to Germany, there get into German journals, and, with "some unpronounceable name," get "translated," as wonderful facts, by some misty writer, by the midnight oil, when they come back again. The thing is completely ludicrous to any one accustomed to the London hospitals, and so-called London journals.

The rage of abuse of the Edinburgh men and Syme has died out, as Syme had the best of it; insurance offices (not the care of the profession) are now the mania; twenty poor physicians were looking for a miserable pittance of £200 a year at Colney Hatch this week, and twice twenty are glad to get £40 and £50 a year; fashionable homœopathy friends of equitable insurance offices meet every day in consultation (some without a diploma in the world), making their £3000 a year.

London, May 21, 1852.

#### MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

DR. J. F. DUNCAN, interim Treasurer, acknowledges with thanks the receipt of the following sums since last report:—

#### COMPLETION OF DR. MURPHY'S MIDWIFERY.

One Vol. 8vo, cloth, with many Illustrations, price 16s.,  
LECTURES ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.

By EDWARD MURPHY, A.M., M.D.,  
Professor of Midwifery in University College, London.

\* \* The "Lectures on Preternatural and Complex Labours and Lactation" are Sold separately (price 7s. 6d.) for the convenience of those who have purchased the "Lectures on Natural and Difficult Parturition."

London: Taylor, Walton, and Maberly, 28, Upper Gower-street, and 27, Ivy-lane.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

*Superior Dissecting Instruments well worth the inspection of the Student.*

**THE COMPOUNDING DEPARTMENT AT**

**G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

**TO PHYSICIANS, SURGEONS, AND DRUGGISTS.**

**BROWN'S CANTHARIDINE BLISTERING TISSUE,**  
PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

**BROWN'S TISSUE DRESSING,**

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

*Extracts and Editorial Note from the New York Journal of Medicine.*

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

*From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.*

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,

"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,

"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

**UNIVERSITY OF LONDON.**

NOTICE is hereby given, that the Annual Examination for MATRICULATION in this University will commence on TUESDAY, the 6th of July.

The Certificate of age must be transmitted to the Registrar fourteen days before the Examination begins.

By order of the Senate,

R. W. ROTHMAN, Registrar.

Somerset House, May 20, 1852.

**MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.**

THE Annual Meeting of this Society will be held on Monday, the 7th day of June, in the College of Physicians, Grand Canal-street.

The President of the College will take the chair at four o'clock p.m.

Members of the Society are particularly requested to attend, and to prevail on non-subscribers to accompany them, that they may be made acquainted with the objects and operations of this invaluable institution.

By order,

W. KINGSLEY, } Hon. Secretaries.  
C. BENSON, }

May 18, 1852.

**ADDRESS TO STEPHEN SWEETNAM, Esq., M.D.**

DEAR SIR,—A recent enactment having severed the connexion which has long subsisted between us, we take occasion to record our grateful sense of your valuable services as the Medical Officer of the Schull Dispensary.

During the past eighteen years, you have performed the laborious duties of that office with a zeal, assiduity, and ability, alike honourable to your profession, and productive of incalculable benefit to our neighbourhood.

Your self-devotion to the cause of suffering humanity during the past years of famine, amidst scenes of appalling desolation, and the unwearied benevolence with which at all times and in all places you ministered to the afflicted, irrespective of every personal consideration, has left an impression not to be erased, while your uniform conduct in all the varied relations of life exhibits an instructive example to all around you.

We pray that Divine Providence may continue to bless your labours, and that His richest mercies may be the un-failing portion of you and yours.

Accept, dear Sir, the accompanying tribute (a Tea Service of Silver) of our sincere regard and esteem, and believe us your faithful servants,

J. Triphook, Rector of Schull.

Richard Evanson.

John Limrick, J.P.

Alexander Cole.

J. O'Callaghan, P.L.G.

Robert Williamson.

W. O'Donovan Williamson.

William Bennett, P.L.G.

A. H. N. Synge, C.O.C.G.

Robert Triphook.

Wm. M. Crosthwaite, Clk.

William Jagoe.

John Sweetnam.

William Swanton, sen.

Charles O'Regan.

John A. Jagoe, P.L.G.

Francis Crowley.

John Evans.

Edward Spring, Clk.

James H. Swanton.

William Long.

Nathaniel Lannier.

William Swanton, jun.

Joseph Driscoll.

William Pier.

**REPLY.**

DEAR FRIENDS,—The address which you have presented to me is so flattering that words can very inadequately convey my feelings; and though the link which has so long connected us is severed, the bond of friendship is but renewed.

That my conduct for so long a period should merit the approbation of men so excellent and benevolent is to me most gratifying; and indeed but for your untiring zeal and support throughout the late dreadful ordeal, my humble efforts would have been vain.

My having "ministered to the sick and afflicted independent of every personal consideration," is but characteristic of the profession to which I have the honour to belong.

Accept then, dear friends, my grateful thanks for past favours, and for the valuable tribute which accompanies your address, and believe me your faithful servant,

STEPHEN SWEETNAM, M.R.C.S. Eng.

Schull, May, 1852.

This is the only Society in connexion with either the Medical or Legal Profession, founded on the principle of MUTUAL ASSURANCE.

This principle is the most beneficial to the Assured, amongst whom THE WHOLE NET PROFITS ARE DIVISIBLE. The Society has a Subscription Capital to guarantee the prompt settlement of claims.

The business of the Society includes—

ASSURANCES, on a Single Life, with or without profits; also on Joint Lives, and on Survivorships.

ANNUITIES, for Lives and Limited Terms, Immediate, and on Survivorship.

DEFERRED ANNUITIES, with the privilege to the Grantees of receiving, in lieu thereof, either their present value in money, or a policy for the equivalent sum at death.

ENDOWMENTS for Widows and Children.

The Society also offers new and distinctive forms of Assurance; as—

ANNUITIES TO CHILDREN, payable from the death of a parent or other person, or for a stated number of years, commencing at a given age.

ENDOWMENTS at all ages.

AND ALL OTHER sound and practicable PROVISIONS contingent on human life, or for terms certain.

INVALID Lives Assured at equitable rates.

### ADVANTAGES OFFERED BY THE SOCIETY.

THE RATES OF PREMIUM, which are founded on the most accurate observations of the duration of human life, are as moderate as is consistent with due Security.

PREMIUMS may be paid either Yearly, Half-yearly, or Quarterly, or in a single payment, or in a limited number of payments, or by an increasing or decreasing scale; or half the Premiums may remain unpaid at simple interest for the first Seven Years, and may be then paid off, or remain as a Debt upon the Policy, at the option of the Assured.

MILITARY AND NAVAL OFFICERS Assured at the ordinary Rates, until called into actual service.

THE AGE of the Life Assured will at any time be admitted on satisfactory evidence being produced.

CLAIMS ON POLICIES will be paid within Three Months after satisfactory proof of Death shall have been produced.

NO ENTRANCE OR ADMISSION FEE, or other Charge beyond the Stamp of the Policy, which may be commuted by a small Annual Payment.

ANY MEMBER wishing to dispose of his Policy, the Directors will purchase it for a sum of Money, payable immediately or at his death; in which latter case the value will be secured by the grant of a New Policy, without further payment, to rank in date as a continuation of the Old Assurance in the future division of Profits.

### PREMIUMS FOR ASSURING £100 AT DEATH.

WHOLE TERM OF LIFE.						
With Profits.			Without Profits.			
Age	Annual Premium.	Single Premium.	Annual Premium.	Single Premium.	Seven Years.	One Year.
15	£1 10 10	£33 6 10	£1 7 10	£30 0 3	£0 16 9	£0 16 0
30	2 6 2	44 2 9	2 1 7	39 14 7	1 5 8	1 3 2

And so on in proportion up to age 70.

Prospectuses, Forms of Proposal, and every further information, will readily be supplied on application, either personally or by letter, to the Actuary, or to any of the Society's Agents.

### MEDICAL REFEREES.

HENRY L. DWYER, M.D., 67, Upper Sackville-street: WILLIAM STOKES, M.D., Merrion-square.

A Liberal Commission to Solicitors and Agents.

N.B.—Medical Practitioners paid by the Office for every case referred to them for their professional opinion.

**Agent—GEORGE B. OWENS, M.D., 25, Kildare-street, Dublin.**

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill.—Wednesday, May 26, 1852.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

A CASE OF HÆMORRHAGE FROM INVERSION OF THE UTERUS, IN WHICH THE OPERATION OF TRANSFUSION WAS SUCCESSFULLY PERFORMED: WITH REMARKS ON THE EMPLOYMENT OF TRANSFUSION GENERALLY.

By JOHN SODEN, Surgeon to the Bath General Hospital.

THE author begins by expressing his belief that the evidence in favour of transfusion is not generally known, and that false notions prevail with respect to its dangerous character. Having had an opportunity three years ago of proving its power, he was induced to examine into the results of all the recorded cases, and has presented a table of thirty-six in which the operation was performed in connexion with the puerperal state. The thirty-sixth case was that in which transfusion was performed by the author. A lady was delivered of her third child rapidly, and the latter pains were so severe that the uterus was violently emptied of its contents, and became inverted; a gush of blood ensued, and the patient fainted. The placenta was detached, and the uterus returned; no further hæmorrhage took place. In half an hour the patient had not rallied, and was insensible, cold, pulseless, and exsanguine in appearance; the breathing was at long intervals, stertorous, and jerking. She could just swallow stimulants by teaspoonfuls at a time, and every other means were used to restore her. After about an hour she became, however, worse; was no longer able to swallow, and the respirations became more rare and stertorous. Transfusion was now had recourse to. The opening was made in the external cephalic vein, and blood drawn from the husband was injected by means of an ordinary syringe of German silver, with a detached stop-cock, previously well warmed. At first the blood would not pass, but returned through the opening in the vein; presently the opposition, from the contact of the coats of the vein, seemed to give way, and the blood, though impelled by a steady and moderate pressure, rushed rapidly up the vein. The effect was instantaneous; a convulsion seized the whole frame, and the

muscles of the face were frightfully distorted: not more than an ounce was injected. The convulsion soon passed off, and the patient gradually recovered; it was full an hour before any pulse could be felt at the wrist, and she did not recover consciousness till the following morning. During this time stimulants were continually given; she remained for some time in a weak condition, but has since had another child, and is now doing well. The author then proceeds to analyse the table of cases, which shows that out of thirty-six cases, twenty-nine were recovered from imminent danger, and it does not appear that in the fatal cases death was due to or hastened by the operation. In two, it may be presumed that death had occurred before the operation was performed; in a third, only a small quantity of blood could be procured; in a fourth, no effect; in the fifth, there were marked but not permanent effects; in the sixth and seventh, the women were too much reduced to be restored. The author considers the influence of the blood injected not to arise from the mere mechanical effect on the heart, but from a direct stimulation of the nervous system, and that the rapidity of the effect is modified greatly by the circumstances of the case, as regards previous duration and cause of exhaustion, and by the character of the means used, as regards quantity, quality, and the mode of operating. With regard to quantity, it appears that a lesser amount was needed in proportion as the exhaustion arose from the suddenness rather than the amount of the bleeding. The author thinks that some cases have been lost from a fear of introducing too much blood, the dangers of which, he thinks, have been over-estimated. The quality of the fluid he regards as of great importance, and he alludes to the impropriety of using the blood of the lower animals. The blood need not be drawn from one individual only; that drawn from many may be taken, but it should be the blood of healthy persons. The want of success attending Dr. Simpson's cases of saline injection in uterine hæmorrhage he attributes to the nature of the fluid used, while the same fluid might be serviceable in cholera, where the quality as well as quantity of the blood is interfered with. With regard to the mode of perform-

ing the operation, the author believes that a simple syringe, with a detached stop-cock, plated or tinned on the inside, and capable of holding about three ounces, is the best instrument. The more complicated instruments constructed to guard against the admission of air, he considers needless, as the danger is an imaginary one. In one case the operation was successfully performed with a common toy syringe. The operation should, however, be performed at the arm or in some distant vein, in preference to the neck, where there might be some risk from the entrance of air. The convulsions which arose in the author's own case, he attributes, not to any irritating quality in the blood injected, but to the transition of the patient from a state of coma to that of syncope; the same thing was noticed in one case three times on the exhibition of stimulants only, and before transfusion was performed. The author then proceeds to notice the opinions of writers on the subject of the treatment of uterine hæmorrhage, and concludes by making a few remarks on the general application of transfusion, which has been equally beneficial in cases of hæmorrhage from other causes, and in exhaustion from inanition. It has been, too, of temporary service in phthisis and in cancer of the stomach. Its use is suggested in the collapse of typhus and in the diarrhœa of children, where exhaustion is threatened.

In reply to a question put to him by the President, Dr. LEE said that he had never seen transfusion of blood employed in any case of uterine hæmorrhage. Having so often of late intruded on the time and attention of the Society, he said he would forbear at present making any further observations on the subject, and now sit down. The Society having expressed a desire that Dr. Lee should state his views on transfusion as a resource in uterine hæmorrhage, he proceeded to observe that in none of the varieties of flooding could he place much dependence on transfusion, and he did not believe that in the case now related to the Society the recovery of the patient could be referred to the introduction of an ounce of blood into the venous system. In accidental uterine hæmorrhage, if the membranes be early ruptured, and where this fails, delivery is completed speedily by turning, the forceps, or craniotomy, and all the means in our power employed to secure uterine contraction, comparatively few women perish; and he (Dr. Lee) had seen some recover where the symptoms were of the most alarming character, and recovery appeared absolutely impossible. In such cases, had transfusion been employed the recovery would have been referred to it, and not to the real cause, the persevering and vigorous use of the ordinary remedies—pressure over the uterus, the external application of cold, and the internal administration of brandy, wine, and ammonia. In the hæmorrhage which takes place after the uterus has been wholly emptied of its contents, the same remedies, if actively employed, are successful in a large proportion of cases. In most of the fatal cases of this description which he (Dr. Lee) had seen, the common practice of introducing the hand into the uterus to excite it to contraction by rubbing the inner surface, had been employed, and he had likewise seen cases where fatal uterine phlebitis could be referred to the same plan of treatment, which is not efficacious in exciting uterine contraction where great exhaustion exists from previous profuse loss of blood. This practice of rubbing the inner surface of the uterus with the closed fist, is not merely inefficacious in the worst cases of atony of the uterus, but it actually displaces those coagula from the exposed vessels which form one of the principal means which Nature employs for the permanent suppression of uterine hæmorrhage. If proper compression be employed over the hypogastrium, coagula can never form to distend the uterus, and like a foreign body, prevent its contractions. Hæmorrhage to a dangerous extent can never, he believed, take place where the uterus is contracted in the ordinary degree. The danger of uterine hæmorrhage from placental presentation is much greater than in the accidental variety; but the mortality has been very considerably diminished in my practice since I observed the fact, that in rigid conditions of the os uteri it is possible to

seize the lower extremities of the child with two fingers, and deliver by turning, without introducing the whole hand through the os uteri. It is deeply to be regretted that an attempt, founded upon a grave anatomical blunder, should have been made to alter the practice established during the last century and a half in unavoidable uterine hæmorrhage. The blood does not proceed from the placenta, as has been asserted, and it is therefore irrational and absurd to recommend tearing it away, or detaching it from the uterus with an iron instrument, and leaving the child within the cavity after being imprudently deprived of life. Some inexperienced practitioners have actually tried this unscientific mode of proceeding. He (Dr. Lee) had great faith in the established rules of practice in all the varieties of uterine hæmorrhage.

#### ON FIBRINOUS DEPOSITS ON THE LINING MEMBRANE OF VEINS.

By HENRY LEE, Esq.

Simple inflammation of the veins—that is to say, inflammation commencing in the coats of the veins—is regarded by the author as a very rare disease. The internal lining of veins especially would appear to be as little susceptible of inflammation as any structure in the body. The large number of instances of phlebitis met with in surgical works, and occurring in daily practice, are regarded by the author as depending upon, and as being excited by, a vitiated condition of the blood. This opinion is principally supported by the two following facts: first, that in every case of so called inflammation of the veins, the blood will be found to have coagulated in the vessels; and secondly, that where such coagulation does not take place, no inflammation will be produced. Continental writers of the highest reputation have indeed mentioned the concentric layers of lymph which are secreted as the result of inflammation in the interior of veins; and English writers whose names carry with them the greatest authority have described the adhesion of the opposed sides of veins by lymph secreted from the capillaries under a state of inflammation. The advocates of this view have particularly referred to an experiment of M. Gendrin, in which he mentions, that by introducing irritating substances into the arteries and veins, he obtained large deposits of lymph upon their interior. The author, on the contrary, having found that inflammation of the coats of the veins only occurred in cases where the blood has previously coagulated in them, was induced to believe that the deposit found in the veins might be derived directly from the blood. M. Gendrin's experiment was therefore repeated, precautions being taken to exclude all blood from the vessel; and it was found that under these circumstances no lymph was effused in the vein. The lining membrane of the veins does not contain any bloodvessels of its own, nor does it require any, being in direct contact with the blood. It appears reasonable to suppose, that under such circumstances it would not secrete lymph, and the experiments and observation of the author lead him to this conclusion. The lining membrane of a vein, the outer coats of which are inflamed, may undergo various changes, or may be disintegrated, and cast off into the cavity of the vessel. Lymph and pus may then be secreted into the interior of the canal; but this can only occur in the latter stages of the disease. The readiness with which some morbid poisons produce the coagulation of the blood, and the constancy with which such coagulation (indicated by the cordlike induration of the vessel) is found to precede the other symptoms of inflammation, lead to the conclusion that a vitiated condition of the blood is the common cause of phlebitis. Under such circumstances, although the irritation produced is caused by the morbid matter detained in the vein, yet the inflammation is at first manifest in the surrounding parts. The cellular tissue becomes distended with serum; the cellular coat of the vein then becomes thickened, red, and inflamed; and finally, the changes which have been noticed extend to the lining membrane. The effects of inflammation thus are shown to extend *to*, and not *from*, the internal surface of veins. M. Cruveilhier, indeed, regards the coagulation of

blood in a vessel as the effect of inflammation previously existing. But the author has satisfied himself, that if blood be prevented from stagnating in a vein, no change will there be produced in its lining membrane. The inflammation is not therefore propagated by continuity of surface, as has been generally supposed, but by the stagnation in different parts of vitiated blood. Coagulation of the blood would therefore appear to be the cause, and not the effect, of inflammation of veins. This view is further supported by the fact, that simple adhesive inflammation of a vein will not produce coagulation of its contents. A preparation was exhibited, showing the effects of a ligature upon a vein twenty-four hours before death. No coagulation of the blood, nor deposit of fibrin on the lining membrane, had in this case taken place. The coats of the vein were thrown into folds, and a white band marked the situation of the ligature; but the projecting folds of the lining membrane presented their natural smooth, polished, and lubricated appearance. Healthy venous blood will remain fluid for days, when confined in a vein by a ligature. In this respect there is a contrast between a vein and an artery. In the latter case, the internal coats are divided, and the blood, coming in contact with the divided edges, immediately coagulates. In the vein, on the contrary, the lining membrane is not divided, and therefore the blood remains in contact only with the natural lining of the vessel. Cases in which a small quantity of pus has been introduced into a vein, afford the strongest contrast to those in which the coats have been mechanically irritated. In the latter case, no coagulum will form, or one only sufficient to unite any lesion there may be of the lining membrane. In the former, on the contrary, extensive fibrinous plugs will occupy the vessels. These will sometimes occupy the whole diameter of the vein, and become firmly attached to its sides; at other times, the outer layers only will become firmly coagulated, and the central ones will remain in a semi-fluid condition. It will sometimes happen that the central portions will be removed, leaving the outer layers attached to the walls of the vessel. The circulation may then be continued through an adventitious cylinder of fibrin. Cases occasionally occur, in which a delicate velvety layer only is deposited on the lining membrane, which remains unaltered in appearance in other parts. The coagula which form in veins will, under such circumstances, lose, in different situations, much of their colouring matter; and it will be observed that the lining membrane of the vein is coloured (from imbibition) in exact proportion to the amount of colouring matter contained in the different parts of coagula. It will occasionally happen that portions of the decolorized fibrin will become organized and intimately connected with the sides of the veins, as illustrated in a preparation exhibited to the Society. Such layers of fibrin appear constantly to have been mistaken for lymph, the product of inflammation. The extreme readiness with which the blood coagulates from the contact of purulent matter, affords a most important provision for the security of the general system. It appears to depend upon a faculty with which the blood is endowed for its self-preservation. This faculty, although hitherto unacknowledged by physiologists, doubtless exists, and is comparable to the preservative sensibility with which every other part of a living being is endowed. When purulent fluid is introduced into a vein, if the coagula are firmly formed, a local inflammation will alone ensue; but if the morbid matter extends along the vessel, a high degree of constitutional irritation will follow, and the symptoms will occasionally bear a striking resemblance to those of typhus fever. In cases as they present themselves in practice, these two sets of symptoms are constantly present at the same time: but they may be produced separately by a very simple experiment: if, for instance, purulent fluid be introduced into a vein, and allowed to remain undisturbed, a local inflammation only will be set up, which will terminate in the formation of an abscess around the vein. The contents of the vein will then become softened, and expelled externally, together with the contents of the abscess. But if the morbid matter be forced forward, in the course of

the circulation, no local inflammation will occur, but the symptoms will indicate either the presence of secondary inflammation in some internal part, or of a general contamination of the blood. If the view taken of the origin of inflammation of the veins be correct, it will be evident that any treatment, to be effectual, must have reference to the first periods of the disease; and that those remedies will most effectually guard the system against the contamination (so much dreaded in this class of cases) which will favour the sequestration of vitiated blood, and tend to localize the disease. The remedies which have been employed to subdue the local inflammation, appear but too often to have done so at the expense of the general system; for although the local symptoms have become less prominent, fatal mischief has appeared in other parts. In severe cases, those remedies only can be safely employed which tend to preserve the power of blood, and especially those which increase its coagulating power, so as to enable it to separate that portion which has become infected from the general circulation. Bark and opium, together with a nutritious diet, are the means which appear to favour these actions, upon the due performance of which the safety of the patient depends; while bleeding and calomel, however useful they might be in a case of simple inflammation of the coats of a vein, appear inadmissible when the disease, as generally happens, originates in its contents.—*Lancet*.

### COLCHICUM IN GOUT.

(From the Second Edition of Dr. Gairdner's Treatise on Gout, lately published.)

It remains that I should now treat of the great specific remedy of gout, Colchicum. My first endeavour must be to remove some prejudices entertained against its employment. These, I believe, spring very much from the old humoral theory of the origin of the disease, which I have combated in the early pages of this work. It has often been asserted that the use of colchicum, however great the degree of relief immediately afforded, tends to the eventual and permanent increase of the disease, and the opinion has even been expressed, that while curing the paroxysm, it lays the foundation of other far more serious evils, and of those heavy accidents which suddenly deprive the gouty of life. That these opinions and assertions are vain and futile may be made evident by considerations of a quite general nature.

The gouty are naturally timid and suspicious, and readily attribute the sufferings they undergo to any preceding events, especially if they happen to be of an unusual kind. Most of them are influenced by the nearly exploded medical opinion of a morbid matter, which must be turned out of the system. Even when they do not rejoice with Sydenham, that the severity of their pain is the best road to health, they still think with Mead, that "gout is the cure of gout," and deem any powerful and rapid interference with the natural course of the disease to be imprudent. It cannot then be wonderful that they should attribute any accident which happens to health and life to the unwise meddling of the physician.

Though I do not think it necessary to undertake the patronage of physicians, and affirm anything in favour of their unerring wisdom, yet patients may see reason to pause ere they adopt an opinion so prejudiced as the above, if they reflect that the accidents, which they attribute to the use of colchicum, are those which spring naturally and frequently from gout, when left unimpeded to follow its ordinary course. We have already pointed out this in the history of the disease. It may indeed be alleged by them, that colchicum aggravates the natural tendencies of the disease; and if this observation be limited to the incautious use of the remedy, and not extended to its total prohibition, it is one in which I very seriously and very earnestly concur.

Having premised these observations, we are now prepared to consider the nature of this remedy, the cases to which it is most applicable, and the limits to be assigned to its use. There is no doubt that colchicum is one of those

drugs, whose claim to be considered is well established. Its effect in freeing the body from disease bears no adequate relation to its immediate visible and tangible, or, as it has been called, its physiological effect on the system. This, indeed, is denied by Dr. Christison, who declares that he has never seen the full benefit of colchicum conferred, till it had produced griping, purging, or some disturbance of the *primæ viæ*. So far as gout is concerned, I am quite sure this is an error. Colchicum never more effectually relieves the patient than when it acts silently and peacefully, without producing any evacuation whatever, or in any way disturbing the patient's comfort and ease.

For this reason, I consider the very smallest dose which will suffice to give us the specific influence of this drug and mastery over the fit, as the most efficacious and the best. A little reflection, however, on the nature of remedies of this class, will, I think, put this in a clear and indisputable light. Narcotics, to which order I think colchicum must be referred, must all be deemed hostile to living bodies. Administered in certain doses they are all poisons. The farther we remove ourselves from this destructive operation, yet retain the virtue of the drug, the wiser surely will be our practice. But the effect of too large a dose is to rouse all the repellent powers of the system for the extrusion of that which is offensive. A smaller dose absorbed into the blood is retained there longer, and has a more permanent as well as more beneficial influence. There is another reason for exhibiting small doses of this remedy derived from its atonic constitution, which will have much weight with scientific chemists. The alkaloids in which the virtue of many narcotic medicines resides, are composed of elements which present a great contrast to the analytic structure of the organic principles of animal bodies. It is difficult to conceive any alliance between them. The former must always be treated as foreign bodies when admitted into the system.

The *modus operandi* of this remedy is not wholly involved in mystery. Dr. Douglas MacLagan, Prof. Chelius, and Dr. Lewins, have demonstrated that it causes a more copious discharge of urea from the system; and it will now, I think, be admitted as an established truth, that the increase of urea is attended by a great diminution of the urates in the urine. The idea, therefore, which I have expressed in another part of this work, receives confirmation here. Urea and uric acid are again found to be correlative and vicarious substances.

This effect of colchicum on the secretion of urine would seem to confirm the opinion of Dr. Holland, that "it owes its virtue in the disease to a specific influence on this secretion." But this is hurrying too fast to a conclusion. The connexion of vitiated urinary secretion with gout is indeed very manifest, and it might, even *à priori*, be expected, that a remedy which puts an end to the paroxysm, should very powerfully affect the symptom in question in common with all others. I fear we are hardly yet prepared to explain the action of colchicum. Longer observation is necessary to solve this difficult problem; but I quite agree with Dr. Holland in the expectation that, from this source, a strong light may be shed on the pathology of the disease. I cannot, however, understand why he should deem it so improbable that the operation of colchicum should be through the nervous system. When I consider how much gout is influenced by the condition of the nervous system, and that the most notable effect of colchicum, whether acting as a remedy or as a poison, is that of a narcotic; and when I further consider the great rapidity of its action, it appears to me probable that the nervous system will be found to be the principal channel through which this medicine exercises its powers. I cannot conceive any medicine capable of removing, in so short a time, all evidence of so much bodily disease and suffering, save one that acts immediately on the nervous system. By what means, indeed, colchicum restores the secretion of urea, and accomplishes that mutation of principles which I have ascribed to the influence of respiration, is a mystery which I cannot thoroughly penetrate. Yet even this appears to me to receive its most satisfactory explanation through the nervous system. I

believe I have made it certain that the heart is enfeebled in gout, and that its action is irregular and spasmodic. All practitioners know the value of narcotics in quelling this desultory action. May not some part of the great effect of colchicum, and of veratrum album, aconite, and opium (all which remedies may often be made coadjutors to, and sometimes substitutes for, colchicum), be ascribed to their power of regulating the action of the heart, so as to induce a better and more even distribution of blood in both the systemic and pulmonic capillaries? But whatever degree of credit may be given to these speculations, it is undoubted that no sufficient explanation can yet be given of the action of colchicum; in other words, it must be classed among specifics.

The cases to which colchicum is most applicable are, without doubt, those of the regular disease, without injury of organs. If there be injury of tissue, so as to argue a destruction of function of any considerable portion of the kidney or liver, the relief to be obtained from colchicum will be problematical. The cases, too, of atonic gout certainly receive less relief from this medicine, and some of them are so little influenced by it as by no means to compensate for the low and depressing feelings it often creates. These effects may, however, be much obviated by combining it with warm aromatic tinctures and waters, and with the vegetable laxatives. The latter do not in the least destroy the specific action of colchicum, but, on the contrary, much promote it. I have often been obliged, in cases which received subsequent relief from colchicum, to renounce the use of the remedy till some defect in the general health, or some local disorder, had been attended to and relieved. But the most common reason of the failure of colchicum is the unnecessarily large dose which is frequently administered. I have often seen quite a poisonous influence from doses carried to the length of producing sickness and diarrhoea. It is true, that this is not a cumulative poison, and if the medicine be intermittent, the symptoms vanish quickly; but the effects of the narcotism induced often remain to such a degree that the patient cannot return to the remedy without a reproduction of his painful symptoms, and its good effects are lost for a considerable time.

I have said that the incautious use of colchicum might aggravate the natural tendencies of the disease, and I feel well assured that many persons have suffered much from, and even paid the heavy forfeit of their lives to, the extreme readiness with which they fly to the relief which this remedy affords. Physicians may indeed dispute about the proximate cause and peccant matter of the disease, but surely no one will doubt for a moment that it has a cause; and it will be granted by most men that the various painful symptoms by which the presence of the disease is manifested constitute an effort by which Nature seeks to relieve herself from a malignant influence, and recover the equilibrium of health. In this sense the paradoxical expression of Mead, that "the gout is the only cure of the gout," contains a great truth. If this be the case, it must surely be apparent to the most careless reasoner, that it can neither be good philosophy nor good practice to use a means which simply puts a stop to a salutary process. Nature seeks a relief *quâ detur porta*, and the physician must not arrive only to forbid it, and to lock up the mischief.

The first bad effect seen from too early an administration of colchicum is that of a total failure of the remedy. The local disease is indeed relieved, but the distress of the patient is in no degree mitigated. His constitutional symptoms remain the same, and in no great length of time an explosion takes place in some other part, in all probability nearer the centre of the system. A metastasis has been effected; but the serious consequence is a prolonged disease; and a prolonged disease is often a great injury to the constitution. If, on the contrary, the disease be permitted to expend its first violence, colchicum may be both safely and effectually used. When the fever has abated, the œdematous swelling of the part been established, and the bowels well relieved, colchicum may be

used with good effect and perfect safety. A long experience of the medicine now enables me with great confidence to recommend to younger practitioners to abate much the amount of the dose they use. I have seen doses of one drachm of the wine or tincture, given twice and three times in the day with no effect on the disease, but with sad disturbance of the patient's constitution; and I have seen the same cases led back gently and quickly to health with doses varying from ten to fifteen minims after a little time had elapsed, and the fire of the disease was in some degree extinguished. If there be sufficient vigour of constitution to permit the practice of a small bleeding, according to the method I have already mentioned, colchicum may be used much sooner, and its administration will generally be attended with happier effects; but I have mostly found it prudent as well as advantageous to pause for a couple of days after bleeding before using colchicum.

Nothing can be more unwise for a patient than, immediately after a cure of gout by this means, to revert to the usual course of life. Yet this is generally done. Indeed colchicum is chiefly valued as a remedy because it permits a speedy return to the pleasures, the occupations, and cares of life. It is of no use to argue with the voluptuary; we might as well lose time with the wretched beings who have lost their reason, or with children who have not attained it; but men who are involved in business would do well to consider how much depends on the use they make of this moment. Some years ago I was desired to visit a gentleman who had just gone through a very painful fit of the gout under the care of a very eminent physician, now dead. He had quarrelled with his doctor in consequence of the troublesome, but very wise, advice the latter had given. I found that the fit, from which this very foolish individual thought he was emerging, had not at all been permitted to run its course. Notwithstanding its duration, no issue had been given to the disease. It had been stopped *in limine* by very heavy doses of colchicum, against all remonstrance on the part of his physician, and the earnest entreaties of his wife: for even she had learned by experience the folly of this course. The consequence was a series of devious and perplexed symptoms, with metastasis to different parts of the body. Each fresh local manifestation of the disease was assailed by a renewed application of the poison. Every absurd error of diet was meanwhile committed. After eleven weeks of this practice I was called to the case, and not permitted the advantage of a consultation with my predecessor.

At this time, however, Nature was operating a cure after a fashion very usual with her. The patient's excesses were restrained by a total loss of appetite; and this continued till the fierceness of the disease was in some degree removed. There was little difficulty in managing him while this state of things remained, but when appetite revived, and his sufferings were in a degree abated, it was impossible to deal with the great perverseness of this man. It was the month of May, and he was eager to go to the clubs, and to parliament, which to him was nothing better than a club. He got well enough to do so, still using, as I afterwards learned, colchicum largely and frequently, and living freely. In this manner he hobbled on till the month of July. I was again desired to visit him. He was a pitiable spectacle of helplessness, pain, and querulous impatience. Nearly every joint was seized. In vain he now attempted to dictate: everything was decided for him. During half of July and throughout August, he underwent indescribable suffering. I believe he had the folly and injustice to ascribe this attack to his physician. I never saw him after the month of October, when he left town, but he died four years after of disease of the heart and hydrothorax. I have been credibly informed, that he continued the use of colchicum with the same imprudence, till it failed in giving even transitory relief, yet did not fail to inflict on him its own peculiar evils.

Cases like the above are of frequent occurrence among weak and pampered individuals who are their own physicians. They stem every approach of the disease in the manner I have related above, convinced that no greater

evil can befall them than the interruption of their habitual amusements. The treatment of such persons is extremely perplexing. Their cases are puzzled and perverted: but the rule of practice is undoubtedly to let the malady return to its regular form, and, no matter what the suffering of the patient, to allow it to exhaust itself. It will leave him less shattered and exhausted, than after it has burst through the impediments which mistaken practice has imposed.

I recommend a perfect holiday to all men who have gone through a fit of gout. It should be passed in good bracing air, with as much exercise as their feeble state will enable them to take, in order that the lungs may be well expanded, the assimilation of the food be perfected, and a pure and well oxygenated blood be worked into the organic textures and moving structures of the body. During this time of seclusion, it is of much importance that a light but nourishing diet should be used, and that the bowels should be gently acted upon, so as to relieve the system of any remaining oppression. These purposes may be well accomplished during a residence at some of the fashionable watering places. The waters of Buxton, Wiesbaden, and Marienbad suit such cases well. If there be much visceral congestion, the waters of Cheltenham, Leamington, Carlsbad, or Vichy are preferable. In advanced cases, with great debility, Kissengen, Pymont, Spa, or Tonbridge may be recommended; and where the fit has left great debility of limb, a visit to Bath or Aix-la-Chapelle will be found profitable. Of these remedies I do not write at greater length; it would require a separate treatise to do them justice.

The local remedies of gout are few, and of little efficacy, yet it is of importance they should be attended to. A dependent position of the affected limb should be carefully avoided. Patients generally make this discovery for themselves, but from first to last, and while any swelling and pain remain, the parts should be kept studiously elevated, so as to favour the gravitation of the blood from the seat of the disease.

The limb should also be kept warm. The great Harvey indeed did not observe this rule, and applied cold to his gout; but his practice is condemned by all physicians of ancient and modern times. I have no doubt of the risk attending it; even when unattended by danger, unless quite inefficacious, it must tend to prolong the attack, to seriously disturb the regular course of the disease, and bring the patient into risk. This will be apparent from a consideration of the nature of the disease.

I have seen much comfort from practice of an opposite kind. When the pain is violent, great relief may often be obtained by wrapping the limb in a poultice; and I have often caused to be placed, with great good effect, underneath a poultice, a rag dipped in tinct. of veratrum, or belladonna, laudanum, or hydrocyanic acid. Instead of a poultice, this local application may be covered with oiled silk, which answers nearly the same end.

Leeches are frequently applied in cases of regular gout, and sometimes, though rarely, with relief to the local suffering. They never, indeed, have any effect, unless the blood they abstract be sufficient to affect the system, for it is through the system that relief is alone possible in gout. But I prefer much to obtain such influence in another manner, which is more manageable and more certain.

The treatment of chalk-stones requires a brief notice. Practitioners are often tempted to open the collections of fetid ichor, very falsely called abscesses, which gather around them. Nothing can be more unwise. No relief to the patient is obtained by the operation, and nearly always a foul, painful, and sometimes dangerous sore is left behind. If let alone, the most unpromising appearances will end in absorption and resolution. The only fit application to them is a pledget of tepid water.

These are the remedies in gout. But let it not be forgotten that they are only remedies for the fit. They who desire to prevent its recurrence, and still more they who look higher, and would eradicate all tendency to the disease, must not depend on the means furnished by pharmacy.

Drugs in this disease only alleviate and shorten suffering. This, however, is much for men who cannot choose either their condition or position in this world, and who, in their pursuits and occupations, must submit to many a hard necessity, little compatible with health. Besides this compulsion of circumstances, it is, I believe, according to the experience of all physicians, that patients much more willingly swallow any amount of medicine, however nauseous, than relinquish long-cherished habits. For my own part, I can truly say that I pass my days exposing the absurdities of custom, and preaching against the noxious lives of my patients.

But before concluding, I would again warn the gouty against expecting too much from drugs. If the functions of the body do not preserve their respective relations,—if the balance of the machine be lost,—disease of one kind or other must be at hand. It is in vain to expect to enjoy health with erring functions, and it is a gross and imperfect view of the practice of medicine which sees disease only in substantial and tangible disorganization of the body's structure. If too much food be administered to the stomach while its assimilation is imperfect, if the primary function of digestion be active while the secondary and equally important one of assimilation is inert, health is impossible for any great length of time. Gout may not, indeed, be the result, unless that unknown something in the constitution, which is the real essence of the disease, be there. But disturbance of health, and possibly organic disease, must ensue.

We are too much accustomed to look upon the bowels as the only road for the excrements of the system. I believe it would be both more true and more wholesome to associate the skin, the kidneys, and the lungs, in this office, and to assign to each of these organs a parity of rank and equal influence in the depurating function. It is certain, however, that if the carbonaceous and nitrogenous principles be not freely and constantly expelled by their proper channels, they must find their way out by vicarious roads, or be retained to disturb the health. Purging is then a necessity for the indolent.

But how much better would it be for those persons to permit the offices of nature to go on in the way which has been ordained for them, to limit their diet and increase their exercise, to take only the amount of food necessary for the sustenance of the body in vigour, and sufficient exercise to keep it in comfort, to direct the nutritious part of the food to the repair of the frame, and to permit the expulsion of all those matters which should go to waste.

#### LARGE OVARIAN CYST TREATED SUCCESSFULLY BY OPERATION.

By Mr. GABB of Hastings.

THE following case presents many points of interest. At the time the operation was performed, it was considered impossible the woman could long have survived, if the plan of repeated tapplings had been adopted. The operation performed was a modification of that proposed by Mr. Bainbrige and Mr. Brown, but the external opening was made lower down than has hitherto been attempted, to facilitate the exit of the discharge, and to prevent the bagging of the cyst below the external aperture:—Mrs. L., aged 32, tall and slight, has been married seven years, has had three children and aborted twice; has never been strong, though enjoying tolerable health; she suffered occasionally, about ten years ago, much pain in the left side, over the region of the descending colon but does not remember if it was worse during the catamenia; menstruation natural up to her marriage. Had a lingering labour with her first child five years ago, and since then has been more weakly, but had nothing particular to complain of. Was confined again in 1849, and had a good time; she remarked, however, that she did not regain her natural size; health much as usual. Her last child was born in January, 1851; labour natural; after which she so rapidly increased in size that it was necessary to tap her in March, and twelve quarts of clear and highly albuminous fluid were removed; recovered quickly. She

again consulted me in October, being much distressed by the reaccumulation of the fluid. Dr. Tyler Smith saw her on the 27th of that month, and it was agreed if on a careful examination, all the other internal organs were found to be normal, to perform the operation recorded.

*Present State.*—Extreme emaciation; the nipple was apparently the only portion of the mammae remaining; thoracic viscera healthy; urine slightly albuminous, probably from the pressure the kidneys were subject to; externally and per vaginam, the tumour (in which fluctuation was peculiarly distinct) occupied the left side. The catamenial discharge (which had just occurred) has been regular since February, when she weaned her infant; she has always remarked that after each period she has got more rapidly larger.

On November 3, at eleven a.m., the following operation was performed under the influence of chloroform, and with the assistance of Dr. Tyler Smith, Dr. Steavenson, and Mr. Ranking:—A vertical incision, about three inches long, was made over the lowest portion of the tumour on the left side, a little external to midway between the anterior superior spinous process of the ilium and pubes and extending nearly as low as Poupart's ligament. The integuments and fascia were cut through and the muscle carefully divided, until the cavity of the peritoneum was opened. The sac (the walls of which were very thin) then came into view, six ligatures were passed through it and the rectus, attaching it closely to that muscle, the fluid was then removed by puncturing the sac with a large trocar, and the operation was concluded by passing a piece of oiled lint into the sac to prevent union and to allow any secretion to escape, and then bringing the edges of the external wound together with sutures, excepting the part left for the plug just mentioned. She bore the operation well. Nine p.m.: Very comfortable and cheerful; pulse quiet. Gave an anodyne draught. 4th. Passed a good night; very comfortable; no febrile excitement. 5th. Going on well. 6th. So comfortable that I did not think it necessary to remove the dressing. 7th. Wound healing by first intention; no discharge. 8th. Passed a bad night; pulse 120; skin hot; troubled much by flatulence and sickness, which she generally suffers from after her confinements; no tenderness of the abdomen on pressure, but a little distended; bowels open; no discharge from the wound. 9th. Removed the plug out of the sac, and about a pint of clear but offensive serum ran out; wound, excepting the part kept open by the plug, nearly well. The only thing she complains of is the distress from the flatulence, which was removed by compound galbanum pill. 10th. Slight tenderness on pressure from peritonitis; sickness; pulse 120; ordered mercury and opium frictions; no discharge from the wound. 11th. Much the same; abdomen tympanitic; sickness still troublesome; no discharge; from the flaccidity of the abdominal parietes the wound is valvular; on removing the dressing an immense quantity of highly offensive gas escaped, and about a pint of serum with flakes of pus; the silver probe was turned black by the secretion; felt much relieved. 12th. Comfortable. 14th. Feels much better; wound discharging freely; fluid of the same character, though less offensive. 16th. Going on well; tenderness gone; about a teacupful and a half of healthy pus comes away in the twenty-four hours. From this date she has progressed satisfactorily, the secretion varying from half to a teacupful in the twenty-four hours. She has lost flesh considerably since the operation. December 31st. Down stairs; is gaining flesh; weighed eighty-five pounds and a half; discharge about two table-spoonfuls daily. February 5th. Has been out for a walk in the garden; weighed eighty-nine pounds and a quarter; about a teaspoonful of discharge. March 11th. Sutures not come away; discharge the same; the probe will only pass downwards, backwards, and inwards; the sore is contracted seemingly to a very small size. The catamenia had not appeared since the operation. On examination per vaginam nothing abnormal can be detected. The urine shows no traces of albumen. 22nd. Weighed ninety-one pounds three-quarters. Since this date she has

steadily continued to improve, and can now take a good walk.

At the request of Dr. Tyler Smith a microscopical examination of the blood, of the fluid which came away when the sac was first opened, and of the fluid which came away at the close of the examination, was made by Dr. H. Jones. The following is the microscopical report made by Dr. H. Jones:—1. "The serum was deeply red tinged, contained fewer blood globules than healthy blood, and they were also apparently feebly formed and less coloured than natural; there were many white or lymph globules, and some granular films of fibrin. 2. The first-drawn fluid contained multitudes of small vesicles, bearing on their walls opaque refracting granules, in number from six to one. I think these were altered blood globules, they were about that size, and had much the appearance that blood globules, when roughly treated, sometimes put on; their membrane was often distinct, enclosing a pale fluid. Along with these there were a very few imperfect granule cells and many tablets of cholesterine; the fluid itself was decidedly coagulated by nitric acid, but did not form a very bulky coagulum. 3. The last-drawn fluid contained a few small flakes of whitish aspect; it was similar to the above, containing altered blood globules. I suppose them to be in abundance, and also cholesterine. The flakes consisted of largish granules apposed together like the bricks in a mosaic pavement; they were perhaps the remains of an altered epithelium. Fat vesicles and cholesterine were mingled with them. All this seems to indicate a low condition of vital power."

April 16, 1852. Upwards of five months have now elapsed since the operation described above was performed, and the subject of it has steadily improved during that time. She was not weighed until she began to improve, but though a tall woman, her weight was only, when it was first taken, eighty-five pounds and a half. She had in three months increased five pounds and a quarter. The comparison between the operation described and tapping, appears favourable to the former. Between the first tapping in March, 1851, and the time when she would have required tapping a second time,—viz., in November of the same year, eight months elapsed. Upwards of five months have elapsed since the operation, and her disease has received a most decided check. The probability is, that had she been tapped in November, the sac would ere this have refilled. The loss from suppuration through the opening into the ovarium is evidently less than the loss from the flowing of albumen and other elements of the blood into the sac. Under the one the patient steadily proceeded in emaciation; under the other, she has gained flesh and strength. But the future progress of the case will require to be recorded.—*Prov. Jour.*

#### TRACHEOTOMY FOR REMOVAL OF A PIECE OF SPONGE.

By E. R. PEASLEE, M.D.

JOHN A. DOBIE, aged about 44, a well-made, robust man, a bookbinder and bookseller, having lost the cartilaginous and also part of the bony septum of the nostrils from a scrofulous affection, was in the habit of introducing a piece of moistened sponge into the nasal passages several times a day to remove the fetid secretion produced by the still progressing disease just mentioned. On the 23rd of July, 1850, while applying the sponge as usual, before entering his shop, immediately after dinner, he accidentally let it slip from his fingers, and it passed back at once through the posterior nares. A paroxysm of coughing, with considerable dyspnoea, at once ensued, and I being hastily sent for, saw him probably within three minutes after the accident occurred, at ten minutes before one p.m. Being told by the patient that he had "a piece of sponge in the throat, I at once passed my finger into the pharynx, expecting to find and dislodge it. Disappointed in this, and being assured by him that he distinctly felt it in the bottom of the pharynx, and just below the point reached by the finger, I then explored that part with the long curved

pharyngeal forceps, and thus ascertained that it was not in the pharynx at all. But he now insisted that my manipulations had carried it farther down, and that he could still distinctly feel it lower and in the œsophagus. His breathing was, however, now much easier, and his cough ceased almost entirely; and I now inquired more particularly as to the precise size of the sponge, he having at first said it was "as large as half a hen's egg." He now placed his right forefinger across the left fore and middle fingers, at the articulation of their first with their second phalanges (thus isolating four phalanges in all), and said "it is as large as that." Of this, on being farther questioned, he said he was "certain." Well knowing his great accuracy of judgment, especially in regard to any mechanical matter, I was inclined to rely on his assertion far more implicitly than I should in the case of most men, and the sequel will show that I was not thus deceived. I next examined a larger piece of sponge, from which the one now producing mischief was taken, and found it coarse and easily torn. Still so large a piece as the patient indicated could not, it seemed to me, be so compressed by any means supposable in the case, as to pass readily through the rima glottidis of a healthy larynx (as there was every reason for believing the patient's to be); or if this had actually occurred, it must still have remained so much condensed, even in the trachea, that the air could not pass so freely to-and-fro in that tube as it did at this moment. I therefore stated to the patient that if his estimate of size were correct, it was "almost an anatomical impossibility" that the sponge could be in the trachea; that I still feared he was mistaken, and it might prove to be there; but that I would be certain it was not in the other passage before I should decide that it was in the trachea. Accordingly, I now passed a feather into the pharynx, hoping a reversed action of the œsophagus might bring up the sponge. Failing in this, and finding he could swallow some water (with some difficulty at first, but more easily at each successive attempt), I next gave an emetic of ipecacuanha. I should here remark that after drinking the water he breathed still easier than before, and said he could feel the sponge passing downward towards the stomach. The emetic operated in fifteen minutes, the fluid contents of the stomach being forced out to a considerable distance, and in a small stream; but the difficulty of breathing at once returned, and the patient said he could again feel the sponge at the bottom of the pharynx, where, however, a second use of the long forceps did not find it. I now obtained, and passed slowly into the stomach, an œsophageal bougie, intending thus to carry the sponge into that viscus, if found in the passage, and at a point too low to be raised by the instruments at my command. Not the least obstruction was encountered till the instrument had passed about half way down the tube, and here it was so easily overcome that I supposed it might be merely a slight spasmodic contraction for the instant. Another slight impediment was met with just before the instrument slipped into the stomach; but this might be owing to the end not precisely entering the cardiac opening at once. But the patient again breathed quietly at once, and said "now I can feel it in my stomach." I was at first inclined to think him correct in this assertion; but as now and then a single "hack" would still occur, the following questions occurred to me, and were reasoned upon as follows: Was the sponge actually at the first point (or the second) of obstruction in the œsophagus, and carried by the bougie into the stomach, as the patient's sensations indicate? or is it actually in the trachea all the while? In favour of the idea that it had been in the œsophagus, it occurred to me that so large a sponge as this was asserted to be, would probably so compress the trachea from behind, if placed anywhere in the œsophagus above the bifurcation of the former, as to cause all the dyspnoea and cough the patient had thus far experienced, and that on carrying it below the bifurcation, that pressure would of course be removed and the dyspnoea with it. The act of swallowing the water might also have carried it below the bifurcation, and thus have relieved the breathing, while the emetic produced the opposite effect in both

respects. Besides the single "hack" which now remains (and seldom recurs) of the cough may well be owing either to the irritation consequent on my manipulations, or even to the presence of the sponge in the stomach. Finally, that so large a sponge could, in the first place, pass into the trachea; and secondly, if there, would produce no more interruption of the breathing than now existed, still seemed improbable. But on the other hand, on the supposition that the sponge is nevertheless in the trachea, I might perhaps have carried it (protruding backward so much) by the bougie farther down that tube, as also the act of deglutition might do; while the act of vomiting might perhaps carry it up against the chordæ vocales, and thus account for the cough and dyspnœa which ensued after it. The ear, applied over the trachea and chest, had detected modifications of the respiratory sounds, varying with the symptoms, but never such as to determine whether the foreign body acted directly or indirectly on the air passage.

It was, however, now certain that the sponge was not in the digestive passage above the stomach, and that if the dyspnœa and suffocative cough should now return, the conclusion must follow that it was in the trachea. I accordingly remained about half an hour longer, but the patient still remaining quiet, I then left to fulfil a consultation appointment. On returning at half-past seven p.m. (I left at half-past two), the patient informed me that during my absence the dyspnœa and cough had returned; that he called in Dr. Crosby, who had also passed a bougie into the stomach, and not finding the sponge, had concluded it must be in the trachea; that Dr. Crosby had advised him to send for me, but on learning that it would be useless, I had so far to go before returning, and that it was the wish both of myself and the patient that he should take the full charge of the case if the dyspnœa returned. Dr. Crosby remarked that he was obliged to leave town that evening in the cars, but would return the next morning at seven o'clock, and then attend to his case. I therefore advised him to keep as quiet as possible during the night, and to sleep in an easy chair; remarked that as it was now sunset, nothing could be done till morning at any rate; that he was in no immediate danger, and would probably have no severer paroxysms during the night than he had already experienced, though the sponge would again, doubtless, change its place. He now had considerably more dyspnœa than when I left him at half-past two o'clock, but no cough. He remained quiet till three o'clock in the morning, when another paroxysm was produced by conversation with his attendant, and I again saw him. It soon passed off after swallowing a small quantity of fluid; but I could now perceive that during the paroxysm expiration was much more difficult than inspiration; after it, inspiration was the more difficult, while previously (in the evening) there was no perceptible difference in the two movements. This suggested the idea that the sponge was raised by the cough, in contact with the chordæ vocales, and that it fell back towards the bifurcation afterwards; but I could not ascertain its precise location by the ear placed over the tube or the chest. On inquiring if he felt exhausted, he replied, "I am not tired, but rather dozy, not having slept much."

I saw the patient at seven o'clock the next morning (July 24th), according to previous arrangement. He had had no paroxysms since three a.m.; had dozed a little, and said, in reply to a question, that he felt strong, but tired and sleepy. The respiratory murmur was now found to be diminished throughout the whole of the right lung, and this side was also evidently less distended on inspiration than the other: the sponge having, probably, at length engaged more especially in the right bronchus. As Dr. Crosby had not come in, I advised to send for him, and have the operation for its removal performed without further delay, and adding that I would gladly be present if informed that Dr. Crosby or himself desired it: I then withdrew.

Soon after eight o'clock, Dr. Crosby sent for me to meet him. The question of operation was at once raised, and no difference of opinion as to its propriety or necessity

being expressed, Dr. Crosby decided to perform it at fifteen minutes before ten o'clock, and desired me to be present.

I have been thus explicit as to all the essential facts and circumstances previous to the operation, when the responsibility of the case passed into other hands, since I have the fullest evidence that even up to the present time they have never, except by a very few, been correctly understood. The patient placed himself as directed, upon a sofa, his head being slightly elevated upon a pillow, and an incision an inch long was made by Dr. Crosby through the skin, and subsequently into the areolar tissue beneath. The parts, however, became immediately obscured by the hæmorrhage; and the incision into the trachea being made under these circumstances, and while the tube was not in a state of tension, was not at first sufficiently extensive. It was, however, rapidly enlarged, and a long forceps passed through it by Dr. Crosby into the trachea, but without finding the sponge. But, in the meantime, the blood, still flowing freely, was drawn into the trachea at each inspiration, had filled the tube, from the sponge up to the incision, and thus completely asphyxiated the patient. It was remarked that the patient was dying, and subsequently added, "he is dead;" when a proposition on my part to try to get the sponge being assented to, I reached after it with the forceps, after rapidly removing the blood with a pellet of cotton, and succeeded in bringing away a portion about as large as a pea; a second attempt secured only a similar result, the mass was so firmly impacted, but the third removed the whole mass, as was supposed at the time, though it will anon appear that a very small portion still remained adherent to the membrane. Still the patient did not begin to breathe again after its removal; but after applying the usual means for exciting the respiratory movements, he at length gasped, and in a few minutes was able to answer questions. The sponge was even larger than the patient had said. Another piece cut out as a *fac simile* of it, but found on accurate comparison to be somewhat thinner and smaller, is, when moistened,  $1\frac{1}{2}$  inch long,  $1\frac{1}{4}$  wide, and  $15-16$  of an inch thick; all this in addition to the three small pieces detached from the original, as before said.

I now expected to take no further part in this case, and learned of Dr. Crosby at half-past twelve that he had closed the wound and just left the patient; but within thirty minutes afterwards I was sent for in great haste (as I resided nearer than Dr. Crosby) as the patient appeared to be dying. I found him breathing with greater difficulty than ever before, livid and insensible, and the neck swollen out almost to a level with his chin, from combined emphysema and hæmorrhage into its areolar tissue. I at once reopened the wound, and on passing a probe down to the bifurcation before finding a spot in which irritability enough still remained to excite a cough, I succeeded in making him expel four ounces or more of fresh blood from the trachea and bronchi, when his respiration and colour again at once somewhat improved. Dr. Crosby coming in soon after the patient was relieved, and learning from me what I had done, and why, remarked that he must leave the patient in my care till night, and withdrew. I then introduced a canula into the trachea, and called several times during the evening to aid him in expelling the blood which still remained in the bronchi, by passing a feather down to the bifurcation, as before explained. During all this time he was at best in a semi-comatose condition; could briefly reply to a question when directly put to him, but never uttered a word otherwise, when I was present. I have no means of knowing the particulars of his subsequent condition. His death occurred on the evening of the 26th of July, about fifty-three hours, I think, after the operation.

*Autopsy.*—An examination twenty-four hours after death was made by myself and Dr. Crosby. Only the respiratory organs were examined, and the following is a *verbatim* copy of the results, as written down at the time:—Larynx large and well proportioned, but in no respect abnormal. Trachea inflamed throughout; a patch of inflammatory exudation just above the bifurcation, equal to

about a square inch in extent; embedded in which, and upon the left side, was a piece of sponge about the size of a common white bean, and so adherent as to detach the membrane when removed. Right lung: very general old adhesions, with inflammation of the upper lobe, and extensive congestion of the others; the bronchial tubes yielded a large quantity of bloody mucus. Left lung: lower lobe inflamed; nothing unusual in the other.—*Buffalo Med. Jr.*

#### ON THE PATHOLOGY OF LEPROSY AND OTHER SCALY DISEASES OF THE SKIN.

By R. B. TODD, M.D.

THE views of the author on the pathology of the squamous diseases are thus expressed:—In discussing this subject, the problem we have to solve is this—What can give rise to these remarkable patches on the skin? why do they assume their peculiar form and other characters? and why do they prefer particular situations of the body? Now we gain an important clue to the decision of this question by our knowledge of the clinical history of syphilitic leprosy. That knowledge amounts to this: by the contact of a certain diseased secretion a primary sore is generated; this is followed by more or less of febrile disturbance, sore throat, articular and periosteal affections, and a peculiar eruption of the skin. It may be taken as quite certain that the cause of all these morbid phenomena is to be found in the introduction into the system of a particular poison. That poison need not be introduced into the system through a mucous membrane; if it be brought in contact with an open surface on the skin, this is quite sufficient to procure its introduction into the system. In this way medical men sometimes become infected, as in a case which lately came before me:—A highly respectable practitioner attended in her labour a woman in whom it never occurred to him to suspect any syphilitic disease. It so happened that at the time he had an abraded surface on one of his fingers. An obstinate ulcer formed here, and secondary symptoms ensued, extending even to disease of the bones. He was at first quite at a loss to explain the cause of his symptoms, when the woman whom he attended applied to him to be cured of secondary symptoms, having an eruption exactly similar to his own; he at once saw the source of his affection. It is through the blood that such a poison must be introduced; there is no other channel through which it can be so conveyed through the system and to such various parts. We learn, then, that a particular poison generated in the body of another may, by its introduction into the blood, create an eruption on the skin which presents characters very much resembling those of common leprosy; and the person in whom the poison is first generated may poison several others, giving rise to the same morbid phenomena in each. Thus a particular modification of the syphilitic poison may produce, by its introduction into the blood, a leprosy eruption on the skin. So, also, other poisonous matters will cause cutaneous eruptions; iodide of potassium will cause an eruption of urticaria or of herpes, or even an eruption of somewhat of the scaly character; mercury will cause a particular form of eczema. The poison of the exanthemata generate each its peculiar form of eruption; and the typhoid poison also occasions a very characteristic rash on the skin. Surely, then, nothing can be more reasonable than to assume that the eruption of leprosy vulgaris, so similar to the syphilitic form and affecting similar parts, is due to an analogous cause—namely, to the presence in the blood of a poisonous agent. But the questions arise, how and where is this generated? can it be isolated? can it be communicated from one to another? To the first question we may answer, that it is generated in the primary and multiplied in the secondary assimilating processes. But as to what gives rise to its generation we can form no definite idea: why it should be generated in one who is fed well and had plenty of work; and why it should also be generated in another who wanted work, and fared wretchedly, are not to be so easily explained. This, however, must not be forgotten as bearing upon these questions,—that an excess of food,

or a supply of a kind of food which is not readily digested by the stomach of the patient in question, may derange the assimilating processes just as much as an insufficient supply of poor food. To the second question we must answer, that the poison of leprosy cannot be isolated, no more than we can isolate the syphilitic poison. But in reply to the third question, it may be affirmed that, although the leprosy vulgaris is not communicable from one to another, syphilis is, yet in another sense, it may be propagated from one to another; I mean that, while it is not contagious, it may be propagated by hereditary descent. And this latter fact, which I suppose the clinical history of leprosy establishes to the satisfaction of even the most scrupulous, is favourable to the view of its pathology which I am endeavouring to advocate. For most—if not all—diseases which seem to arise from a *materies morbi* in the blood, are apt to be propagated by hereditary descent. Another feature of these scaly diseases which favours this humoral view of their pathology is the disposition which the eruptions manifest to affect the skin symmetrically. Many diseases referable to a *materies morbi* exhibit this tendency to symmetry; as has been shown by Dr. W. Budd, in a most valuable paper in the *Medico-Chirurgical Transactions*, in which he discusses with great ability the pathology of leprosy and psoriasis. To conclude, then, this part of my subject, which time forbids me to treat of at greater length, I would sum up thus: that as the syphilitic leprosy is due to the introduction into the blood of a poison generated in the body of another as the result of impure and promiscuous sexual intercourse, so the leprosy vulgaris is produced by a poison generated in the body of the patient—an effect of some disturbance of the primary and secondary assimilating processes; or of which the germs, as it were, were transmitted from either parent, and were multiplied in the secondary assimilating processes of the patient.—*Med. Gaz.*

#### LARYNGOTOMY SUCCESSFULLY PERFORMED IN A CASE OF FOREIGN BODY IN THE LARYNX.

By G. R. MOREHOUSE, M.D., of Philadelphia.

THE little patient, a girl of 10 years, daughter of Mrs. Saunders, on Wednesday morning, February 26th, while laughing and romping with her school-fellows, drew into the larynx a piece of almond shell which she had been holding in her mouth. She was immediately seized with a prolonged paroxysm of coughing, followed by dyspnoea and loss of voice. As soon as aid could be obtained, she was carried home, and Drs. Scofield and Gegan successively sent for. Under their hands every medical means for disengaging the shell was tried, the œsophagus also was explored, and instruments used to force anything contained therein into the stomach, but every effort seemed in vain. The dyspnoea increased, and the paroxysms of cough became more incessant and more fatiguing. The only remaining mode of relief was the removal of the foreign body through an opening in the windpipe. Accordingly, on Thursday afternoon, I was called to see the child and operate if advisable. At that time the condition of the little sufferer proclaimed the necessity for immediate relief. The face was turgid and of a purplish hue, the eyes protruding, and slightly divergent, the mouth circled with a white zone, and the nostrils distended and pale, forming a countenance expressive of mingled anxiety and despair, the head was inclined forward, and the muscles of forced inspiration strongly contracted, giving to the neck the appearance of great emaciation. Deglutition seemed unimpaired, and she was able, with apparent ease, to gratify her craving thirst. Respiration was with difficulty maintained, and was accompanied with a wheezing sound similar to that heard in asthma, although much more feeble. She complained of no pain except when lateral pressure was made on the larynx. She seemed disinclined to exertion, except at intervals, when her motions were hurried and restless. She seemed fully to appreciate what was passing around her, and spoke to her friends in whispers, repeatedly expressing a wish to die.

Upon auscultation, the respiratory murmur, although

barely discernible, was found alike free in either lung; there was no rattling sound to indicate the presence of a loose body in the trachea. Over the larynx, however, a whistling sound, as of a person blowing through a quill, was distinctly heard. These facts, therefore, the incessant cough, the dyspnoea, the pain on pressure, the whispering voice, and the whistling sound of constriction, all pointed to the ventricles of the larynx as the position occupied by the foreign body. By the time that these necessary examinations were made, and the mother's consent to the operation obtained, it had become too dark to operate without the aid of artificial light. The extreme condition of the patient, however, rendered it necessary that an opening at least should be made in the windpipe to prevent death from apnoea. The operation of laryngo-tracheotomy, as originally suggested by Boyer, was selected as most appropriate. The patient was placed upon the table, and an attempt made to commence the operation. The violent convulsive struggles of the child, and the forced forward flexion of the head, rendered it impossible to proceed. Ether was therefore administered, sufficient to quiet, without producing its full anæsthetic effect. The superficial tissues were then divided in the middle line by a cut nearly three inches in length, the isthmus of the thyroid body was separated from its attachment, and the plexus of thyroid veins pushed aside with the handle of the scalpel. The windpipe thus being laid bare, and the hæmorrhage slight, as soon as the effect of the ether had passed away, the knife was entered just below the crico-thyroidean artery, dividing, as it was withdrawn, the cricoid cartilage and three upper rings of the trachea. The air rushed from the wound as soon as the knife was removed, blowing before it the blood which flowed from the cut. The patient was raised and placed in a position favourable for the outward flow of the blood.

The relief experienced by the child was immediate and most gratifying, the black blood sunk from the face, the asthmatic breathing ceased, the labouring muscles were at rest, and the countenance, a moment since livid, swollen, and inexpressive, was now lit up with a smile of gratitude. As soon as oozing had ceased, examination was made for the foreign body, and it was found effusion had taken place in the submucous tissue, almost obliterating the cavity of the trachea at its upper portion. So great was the swelling that it was impossible to introduce an instrument through the rima glottidis, with the hope of extricating the shell; it was therefore proposed to continue the incision upward and divide the thyroid cartilage. On account of the prostrate condition of the child, however, and in hope that the œdema would subside and render the extension of the operation unnecessary, it was concluded to defer the division of the cartilage until the morning. In the meantime a conical curved tube, flattened laterally, was introduced through the opening, and secured by means of tapes passed round the neck. An anodyne was administered, and the patient left for the night.

On the following morning, the appearance of the child was propitious, she had rested well during the night, being troubled but little with cough; the tube had occasionally clogged with mucus, but was readily cleared with a feather. The œdema in the trachea had greatly subsided; the chords were, however, in apparently as close proximity as ever. It was decided therefore to open the thyroid cartilage, and for this purpose a probe-pointed bistoury was prepared in the following manner: A coating of wax was applied to the sides of the blade, thus converting it into an edgeless instrument, which, having passed between the lips of the rima, would glide along without injuring them to their junction with the thyroid cartilage. The bistoury thus prepared was entered at the previous opening, passed between the chords, and with it the cartilage divided. The crico-thyroidean artery was cut, but was readily sealed by the application of a point of caustic. The cartilage was pressed asunder, and the piece of shell removed from the left ventricle by means of a pair of polypus forceps. The tube was permitted to remain in the wound until the swelling of the glottis had subsided, which could readily be

judged of by the facility of breathing when the tube was closed. On the second day the tube was removed, and the wound closed with stitches and adhesive plaster. In order that the sides of the wound might be brought in apposition throughout their whole depth, a compress of a double headed roller was employed, the roller (half an inch in diameter) pressing parallel to the cut on either side, and bound to the neck by means of a bandage. The cut has healed kindly and rapidly: the water dressing was used, and parts of the surface occasionally touched with nitrate of silver. The wound was entirely healed on the 12th of March, fifteen days after the operation, the child's voice is as clear as ever in the morning, but towards evening is somewhat husky, especially if she is disobedient and talks much during the day.—*Phil. Med. Examiner.*

## ON THE ACID REACTION OF THE URINE.

By Professor C. G. LEHMANN.

THE following paragraph contains a summary of all that is known regarding the acid reaction of the urine:—

The cause of the acid reaction of normal urine long remained obscure. This acid reaction was formerly attributed to the presence of lactic acid, and even of acetic acid. Liebig has, however, investigated the subject, and shown that it can only be dependent on acid phosphate of soda. If we dissolve ordinary phosphate of soda in water (thus forming a solution with an alkaline reaction), and gradually add uric acid (which has no reaction on vegetable colours), and apply heat, we obtain a fluid which reddens litmus, and which, on cooling, deposits a white, crystalline powder, presenting under the microscope the most beautiful groups of prismatic crystals of urate of soda. Now, if so weak an acid as uric acid can abstract a portion of its base from phosphate of soda, there can be no doubt that stronger acids, as hippuric, lactic, and sulphuric acids, directly on their formation in the metamorphosis of animal tissue, convert the neutral phosphate of soda into an acid salt, in which form it passes with the sulphate, lactate, and hippurate of soda into the urine. If the acidity of normal urine generally can be explained in this manner, the fluid should never saturate more base than corresponds to its quantity of phosphate of soda. The experiments which have been made to elucidate this point are, however, not so easy to conduct as might at first sight appear; for after treating urine with an alkali till there is neither an acid nor an alkaline reaction, it will still contain acid phosphate of soda in solution; for the neutral phosphate of soda has an alkaline reaction, and therefore the acid salt (if the urine exhibits no reaction on vegetable colours) is still not neutralized. I have endeavoured to ascertain the quantity of free acid in the urine in the following manner:—The urine was precipitated with an excess of chloride of barium, the precipitate boiled with water containing sulphuric acid, and the weight of the sulphate of baryta determined; an equal quantity of urine was then digested with freshly precipitated carbonate of baryta, till all acid reaction had disappeared; the filtered fluid was then acidulated with a little acetic acid, and precipitated by chloride of barium; this precipitate also was washed with water containing sulphuric acid, and weighed; the quantity of the latter was far less than that of the first weighed sulphate of baryta, the difference of the weights corresponding to a quantity of sulphate of baryta whose base had been exactly sufficient to saturate the free acid contained in the urine; hence we can readily calculate from the chemical equivalents the quantity of the free acid or of the acid phosphate of soda. Now, if the calculation thus made did not give more acid phosphate of soda than was shown by a differently made analysis to be actually contained in the urine, the acid reaction of the urine would be *alone* dependent on the acid phosphate of soda. This was certainly often the case; but both in healthy and in morbid urine I frequently met with the opposite condition; that is to say, in comparing the baryta-salts, the quantity of acid phosphate of soda which was calculated was more than that found by direct analysis; hence, in the majority

of cases, in addition to the acid phosphate of soda, the urine must contain a free organic acid, or another acid salt capable of reddening litmus. We must not, however, arrive at our conclusions too rapidly, for the acidity of the urine after its discharge often increases so rapidly from the formation of lactic or acetic acid, that the excess of the free acids found in the above experiments might depend on lactic acid developed in the urine after its excretion. In morbid urine, however, we often find so great an excess of free acid over the phosphate of soda, that to these cases the above objection cannot be applicable. The acid reaction of the urine depends, therefore, in many cases, not only on the presence of acid phosphate of soda, but also on the presence of hippuric and lactic acids. If there were only acid phosphate of soda present, the phosphates of lime and magnesia in the urine could only be held in solution either as acid phosphates or by another free acid. If, in the above calculation of the free acid from the precipitated baryta-salts, the earthy phosphates are included in the weighing, the result always remains the same; that is to say, there is more free acid than could be derived from all the acid phosphates of the urine. The water-extract of the urine usually has an acid reaction after repeated washings with alcohol, and solely on account of its containing acid earthy phosphates; these must, however, also be present when lactic or hippuric acid is the acidifying principle of the urine.—*Brit. and For. Med. Chir. Rev.*

#### MEDICAL GLEANINGS FROM THE AMERICAN ARCTIC EXPEDITION.

By B. VREELAND, M.D., United States Navy.

WE sailed from New York on the 23rd of May, 1850, with a crew that had been promiscuously obtained, and whose physical strength was not well adapted to withstand the hardships to be expected on the cruise. Several of the men were even suffering from chronic affections, and but few of them possessed that robustness which the service demanded. The majority of the officers and crews, however, were much nearer twenty than thirty years of age, and had all the endurance and enthusiasm natural to young men. The total number of souls on board both vessels was thirty-five, of which eight were officers. The vessels were very small; of one hundred and fifty, and ninety tons burden, respectively, and were actually so loaded down with provisions, that at sea our decks were constantly washed by water ankle deep, which often poured down the hatches of the cabin and fore-castle. The quarters of the officers and men were necessarily confined, and as no fire was placed below until late in the fall, their dampness and bad ventilation caused great inconvenience and discomfort. During the voyage out to Baffin's Bay, almost all suffered from bronchial and rheumatic affections; in one case a relapse of intermittent fever was undoubtedly brought on by these unfavourable circumstances, and the rawness of the climate produced crops of chilblains, covering the hands and feet, that were exceedingly painful and annoying. We arrived at our first rendezvous, the Whale Islands, in 69 deg. north latitude, on the 27th of June, and, after a delay of two days, sailed and made the packed ice on the 7th of July. From this date to August 16, when we reached the north water in Baffin's Bay, in latitude 76 deg. north, we were constantly exposed to the numerous sources of disease necessarily attendant upon the tedious and dangerous labour of navigating the vessels through the ice. The ships' companies were worked in watches without intermission, and it not unfrequently happened that all hands were employed for twenty-four hours in succession, in heaving, warping, breaking, and sawing through ice from one to eight feet in thickness; the weather during the time being generally foggy and unpleasant, and the thermometer ranging from 25 to 42 degrees, Fah. While thus engaged, the feet were continually wet, and the clothing damp, from being obliged to wade through pools of melting snow. It was a common accident for individuals to fall overboard, and be entirely immersed in water, the temperature of which never ranged higher than

32 degrees, and frequently was as low as 28 degrees. When an accident of this kind occurred, assistance was immediately required to get the person out, for in a short time he became so benumbed as to be unable to help himself. Fortunately, we had not much sickness while exposed to this cold, wet, and fatiguing labour. The change and drying of wet clothes was required of the men as fast as practicable; but the means were so scant, and opportunities so few, that many were obliged to wear their clothing imperfectly dried. In consequence, colds and rheumatic pains were frequent, and to that cause the early appearance (on July 25) of a case of scurvy was particularly attributed, the young man who was attacked being discovered to be very negligent and careless in that respect. On the 13th of September, the temperature falling to 8 degrees, the vessels were frozen in at the entrance to Wellington Channel, in 74 deg. north latitude, and 93 deg. west longitude, and our position was so uncertain and so perilous, owing to the rapid drift and crushing of the ice, that preparations for the winter could not be made, and stoves were not erected until the 19th of October. In the meantime the thermometer had fallen to 11 degrees, and the discomfort experienced at that period surpassed any that was felt during the remaining portion of the winter. It was impossible to keep warm without constant exercise; the vapours arising from our bodies condensed on the timbers, bulkheads, and in our sleeping places; first as water, rendering them very wet and unwholesome, and, as the temperature decreased, in the form of ice and snow. The only fire, since leaving New York, had been kept in the galley on deck, where the necessary cooking operations were performed. No clothing or bedding could be carried on deck for the purpose of ventilation, for, on being returned below, the surrounding vapours would immediately condense upon them, and render them much more wet than before. Metallic bodies brought below from the external atmosphere, would be instantly covered with a sheeting of ice. Scurvy began to appear in earnest on the 28th of September, and continued among us until our disruption from the ice in the beginning of June, 1851. Disease was to be expected under such circumstances; and that we suffered so little serious sickness as we did, may perhaps be attributed to the constant exercise we were obliged to take in order to maintain a necessary amount of animal heat. It was not until the 1st of November that the "Advance" was ready to receive the officers and crew of the "Rescue" for the winter. Everything was done that could render the vessel as comfortable as she possibly could be. The stores were taken from the hold, and placed on the decks of the "Rescue," and the whole interior was open and unconfined by partition or bulkhead. The galley was placed on the keelson amidships; forward of which were the men's quarters, in which was a stove; and aft, the officers', where another stove was situated. These three fires were sufficient to give us a comfortable heat during the most intense cold of winter; the thermometer placed near the centre of the vessel averaging about 60 degrees. This temperature prevented all condensation in the open parts of the vessel, but in the lockers and on the metallic fastenings at the sides, water and ice was continually forming. A constant and effectual ventilation, although absolutely necessary, was impracticable; but in order that there might be some escape for the impurities generated below, the cabin hatch was always kept open, notwithstanding which we were obliged to breathe lamp smoke and coal ashes during the whole winter, and in such quantity that we never expectorated without bringing up these substances in great abundance. The sun left us on the 7th of November, and did not appear again until the 28th of January, a period of seventy-four days. After the sun had set, cases of scurvy increased rapidly, but the symptoms never progressed so far as to produce any serious apprehensions. Not a man was ever confined to his bed, and although some were lame, and unable to use one lower extremity, they were always, during the time appropriated to exercise, compelled to take a certain quantity in company with their messmates.

The causes which seemed to have a direct influence in producing and prolonging the cases under our observation were, the long absence of solar light, a diet without change or variety, want of proper exciting exercise, personal uncleanness, dreary monotony, and consequent depression of spirits. The symptoms were generally uniform, almost always the first change noticed being a peculiar white arch on the gums, at the root of one or more of the incisor teeth in either jaw, followed in a few days by sponginess, lividity, ulceration, and bleeding. Subsequently, the lower extremities would become painful, swollen, indurated, and discoloured by ecchymosis. Sometimes the legs would have the appearances above described, at the same time that the gums continued perfectly healthy. Irritation of the rectum, with frequent small, slimy, and bloody stools, accompanied by pain and tenesmus, was also frequent. In December, our boatswain's mate, aged about 50, the oldest man in the vessels, was seized with pneumonia, which at one time seemed likely to prove fatal, but he gradually recovered, and during convalescence suffered severely from ulceration and loosening of the gums, brought on by his long confinement below. We had but one severe case of frost-bite, in which a part of the helix of the ear sloughed away. Superficial frost-bites, however, causing vesication of the fingers, nose, ears, and cheeks, were continually occurring. If the slightest wind was stirring, the ends of the nose and the lobes of the ears of some of us would freeze, and we would remain unconscious of the fact until informed by a companion. In the spring, several of the officers and men were rendered snow-blind by the peculiar glare of the snow which exists in overcast weather. On bright sunshiny days, we walked on the dazzling ice and snow with impunity, but when the sky was at all obscured by clouds, the light reflected from the snow was such as to deceive us as to the true distance and size of objects; and the unevenness of the surface of the ice was so disguised, that we were unable to tell an elevation from a depression; consequently we would step off from pieces of ice three or four feet high without being conscious of any change of surface until we found ourselves falling; and again, we would trip over inequalities that were insensible to us until it was too late to raise our feet high enough to clear them. This indistinctness and uncertainty of vision brought on a very acute conjunctivitis, that for thirty-six or forty-eight hours was very painful. The most grateful application was cold water, and in four or five days the eyes were apparently as well as ever. The relations between the officers and men were of the most easy and pleasant nature, privations and hardships were shared alike by all, and the few comforts we were possessed of, equally distributed and enjoyed. The discipline practised during the winter had direct reference to the preservation of the vessel and the health of the crew, and was so apparent to every man, that its importance was always appreciated. But little difficulty was experienced in enforcing obedience, and a murmur or complaint was rarely heard. The daily ration for each man, for four days in the week, consisted of one pound of fresh beef or mutton, and three quarters of a pound of preserved vegetables, either potatoes, carrots, or beets. On the alternate three days, one pound of salt pork or beef was issued, and in addition, all the other articles of the navy ration. A liberal supply of vinegar, pickles, and preserved cranberries was allowed, and an abundance of well fermented bread was made daily. The fresh provisions had been previously cooked, and preserved in tin canisters, hermetically sealed, and at first were quite palatable, but in a short time they became insipid and tasteless; and towards the close of the winter, such was the disrelish and disgust for them, that not one half of the ration was eaten. A little variety in the way of bears' and foxes' flesh was now and then obtained, and enjoyed exceedingly. They were considered luxuries, and mostly appropriated to the scorbutic, upon whom they seemed to have an excellent effect, merely by the change in diet which they afforded. The men's gums and shins were daily examined, and their personal cleanliness strictly inspected, as also the condition of their

apartment, in regard to its dryness, cleanliness, &c. At the same time, from two to four ounces of lime-juice was made into lemonade, and taken by each man in the presence of one of the medical officers. The officers generally drank about the same quantity at dinner. Daily exercise was one of the most important duties to be attended to, and as there was always sufficient light for about four hours in the middle of the day to enable us to walk a mile or two from the vessel, and play at various games, such as football, skating, sliding, &c., every man was required to engage in them. On board, reading was the chief occupation; and when this grew wearisome, cards and games of all kinds were resorted to, to relieve *ennui*; and once every fortnight, theatrical entertainments were given by the crew, under the encouragement and zealous assistance of the officers. The latter amusements were well adapted to enliven the sailors, for they gave pleasant excitement and employment for days in succession, in preparing roles and in manufacturing dresses, scenery, &c. It may be a sufficient proof of the interest which these plays created, and the infinite amusement they afforded, to say, that on the very coldest night of the winter, we sat on deck, viewing and applauding representations in which female characters appeared on the stage with bare necks and arms when the thermometer was 46 degrees below zero. Towards the end of the long nights, a loss of flesh and of strength was observable in all of us; we had become bleached to a pale waxy colour, and our hair came out abundantly. The antiscorbutics, in a measure, lost their effect, and possessed but the power of holding the disease in check, for symptoms did not begin to disappear, and cases to recover permanently, until after the rising of the sun: the exhilaration excited by his reappearance seemed to have a direct and beneficial influence. Out of the whole complement, one officer and nineteen men had unequivocal symptoms of scurvy. The remaining seven officers and seven men enjoyed comparatively good health during the whole cruise. The disruption of the ice on the 5th of June, in north latitude 66 degrees, and west longitude 59 degrees, liberated the vessels, and with all possible despatch we made the first convenient settlement on the coast of Greenland. Here we obtained fresh fish, seals, and scurvy-grass, by which the health of the ships' companies was recruited, and their strength partly restored. But we felt conscious and it was evident from our altered appearance, that we did not possess the vigour of the preceding year; and the probability is, that if we had been detained another winter in those regions, a number of our party would not have survived it. We then proceeded north again, with the intention of continuing the search, but being unable to penetrate the ice in the northern part of Baffin's Bay, and having waited for an opening until the 18th of August, we made sail for home, where we arrived on the 7th of October.—*Buffalo Med. Jour.*

#### CASE OF CONTRACTION OF THE STOMACH.

By THOMAS DALE, L.S.A., Liverpool.

Mrs. E. M.—, aged 48, married, mother of seven or eight children, was placed under my care October 2, 1851. She is a very thin, delicate looking person, of a scrofulous constitution. For seven or eight years, during winter, she has had a cough and difficulty of breathing. In May, 1849, she had an attack of cholera, and since has suffered frequently from a severe pain in the left side, about the cartilages of the false ribs; on which pain nothing seemed to have any effect but stimulants and pressure, or food taken into the stomach; her appetite, however, was poor, that she could seldom eat anything. In the summer of 1850, she occasionally ejected from the stomach a grumous sort of matter, after which she was easier for a week or two.

Her present symptoms are—severe pain in the left side, loss of appetite, constipation, weak pulse, numbering about 100 in the minute, cough, occasional dyspnoea, puerile respiration in both subclavian regions, and in the right scapular, large crepitation, pectoriloquy, and dulness on percussion. Nourishing diet, stimulants, and sedatives

were ordered, which for a while gave some relief, but ultimately lost their effect. She gradually sank, and died March 1, 1852. A post-mortem was made sixty-four hours after death. The right lung has numerous adhesions to the ribs and diaphragm, contains two cavities, one in the upper lobe and one in the middle lobe. Tubercular matter is also deposited throughout the greater portion of the lung. The left lung has a few adhesions, and contains a few crude tubercles. The heart is very soft and flabby; the liver fills the right hypochondriac and right lumbar regions; the gall-bladder contains no bile, but two gall-stones, each about the size of a hazel-nut, and many smaller ones, probably two or three hundred. The stomach is constricted about midway between the cardiac and pyloric orifices, forming two sacs of about equal size, with a communication half an inch in diameter. The cardiac compartment has a healthy appearance; the pyloric, near the stricture, is rather vascular; there is not any evidence of ulceration, nor indeed of any diseased action beyond the vascularity and stricture. The great omentum is firmly adherent to the right iliac fossa. The caput cæcum coli is unusually capacious; the transverse colon is much narrower and its coats much thicker than natural; the small intestines are, in places, highly vascular. All the other organs are in their normal state.—*Lancet*.

The writer of this seems to be entirely ignorant of the information extant on the subject, and not aware that this hour-glass contraction has attracted the attention of anatomists. Where is it that such people are taught?

#### A CASE OF POISONING FROM THE EXTERNAL APPLICATION OF COCCULUS INDICUS.

By WM. B. THOMPSON, M.D.,

House-Surgeon to Emigrant's Hospital, Philadelphia.

BRIDGET MADDON, aged 6, native of Ireland, blue eyes and fair complexion, was admitted into the surgical division, accompanied by a sister and brother, on the evening of the 2nd of February, 1852, labouring under porrigo of the scalp, infected with vermin. The nurse was directed, after cutting the hair close, to wash their heads with an infusion of delphinia (the house prescription). Not having the article at the time, the apothecary sent an infusion of cocculus indicus (used in the hospital for the same purpose), made by displacement—a pound to three gallons of dilute alcohol—six ounces of which were used for the three children. Half an hour after its application, I was sent for to see Bridget, whom I found labouring under tetanic spasms, with the pupils contracted to their smallest diameter. As the spasm abated, the pupils became dilated to their fullest extent, and again contracting as the spasm returned. By touching the eyelids, the spasm could be produced at pleasure; this was repeated until all present became fully satisfied the difficulty was seated in the excito-motory system, and was the result of irritation rather than inflammation. The case was treated as one of idiopathic tetanus, with counter-irritation, warm baths, and antispasmodics; but the attacks continued to increase in frequency and force until the patient sank about midnight of the same day. A post-mortem examination was made of the body thirty hours after death. The viscera, brain, and its appendages were minutely examined, and all found to be in a healthy condition. The nature of the case is confirmed by the younger sister, aged 4, being attacked in the same manner and exhibiting the same symptoms as she (Bridget) did. Being in the ward at the time, a warm bath was ordered, into which she was placed as soon as the first spasm was over; a mustard plaster was applied over the abdomen and to the legs and feet as high as the knee; injections of the tincture of assafoetida were thrown into the rectum, and a few drops administered by the mouth every hour. By persevering with these means the spasms subsided gradually after an elapse of three hours from the commencement of the attack. On the morning of the 4th, the patient's body and arms were again covered with an eruption resembling scarlatina, which gradually faded away during the day.—*Phil. Med. Examiner*.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JUNE 2, 1852.

### UNIVERSITY REFORM.

OUR prospects brighten as to this most important object. The Report of the Oxford Commission is out; and, ■ our contemporary below quoted says, they really "have made a report" notwithstanding "the scruples which have led so many respectable men to withhold the information at their command." The Report is valuable for the information it contains, as well as for the reforms and improvements it suggests, and doubly valuable as conclusive evidence that institutions of this nature are no longer to be considered invulnerable. To us here in Ireland its appearance must be most gratifying, while a similar Commission is making similar inquiries as to similar causes of complaint regarding Trinity College, Dublin. Whatever misgivings have hitherto existed as to the firmness of the Dublin Commissioners in the prosecution of their labours, they must be now dispelled; for it is obvious that no political rallying-cry can muster to the rescue any force sufficient to intimidate those entrusted with the duty in question. It is equally obvious that, in the teeth of such decisive evidence as this, no doubt can be entertained of the existence of a determination in high quarters to speed this inquiry. We copy the following from the *Times* newspaper, in which it appears as a sketch of the Report, ■ well as a hint to the parties concerned. On future occasions we propose to return to the subject, which, we are convinced, is one of great importance to our profession:—

The Report of the Oxford University Commission, which has so long been feared or desired, was published yesterday. It is a bulky volume, running to nearly 800 folio pages, of which more than 250 are devoted to the Report itself, arranged under the several heads of the state, the discipline, the studies, and the revenues of the university and the several colleges and halls, summed up with a very compendious "conclusion." The remainder of the volume consists of some legal and historical statements, correspondence, tables of fees and other documents, and the evidence of ninety prelates, dignitaries, professors, distinguished men, and university and college officials—the so-called evidence assuming in some instances the character of considerable pamphlets, and in others being confined to the formal receipts of the circulars issued by the commission. This superficial account of the volume will satisfy the most sceptical member of the university that the commissioners have made a report, and that they have not been entirely paralyzed by the scruples which led so many respectable men to withhold the information at their command. The commissioners express their regret that, owing to these scruples, the report is not quite so complete ■ might have been desired, but no one can turn over the leaves without perceiving that there is quite enough, not merely to satisfy a large curiosity, but also to supply the necessary materials for legislative discussion. After all, those palpable facts of the case that are before the eyes of the whole world, and which constitute the operation and results of the university system, are the most important; and, as far as we can see, they are fully brought out in the pages before us. As it is, the commissioners feel it necessary to apologize for the length of their report. Though it is the object of many of the recommendations rather to emancipate the university and colleges, and enable them to extend their utility themselves, and though it is rather ■ beginning than ■ complete system which is suggested, yet the commissioners have gone quite as far as was desirable, or perhaps possible, in filling up ■ scheme of reform. That proposed reform is serious, extensive, and particular. Indeed, there is not ■ office or an institution or a practice in the university, from the appointment of the vice-chancellor to the debts of the undergraduates—from the government of the university to the time of the long vacation, which is not affected. The

mere summary of the proposed alterations extends to 47 heads. Whatever difference of opinion there will be as to the merit of this or that proposal, there can be no difference as to the conscientious spirit in which the commissioners have discharged their sacred trust. They propose to give the university, with proper reserves, full power of self-government. To carry this power into effect, they propose to create a senate, preserving the name of the "Congregation," consisting of all heads of houses, the proctors, all professors and public lecturers, together with the senior tutors of all colleges and halls, and to give this body authority to originate measures, and power to appoint delegacies, or standing committees, for special purposes. This body is proposed rather as an addition to the existing branches of the academic legislature, the hebdomadal board still retaining its executive powers and its right to originate measures, and the convocation still having that *veto* into which prescription has narrowed its functions. Such an addition, however, has long been required, and till recently its place was supplied by a species of mixed committee or conference, that mediated between the hebdomadal board and the convocation—the lords and commons of the university. It is proposed to give the most important functions of the university, the supervision of studies, the appointment of examiners, and the management of the public libraries, to the professorial body alone, that body, however, being very extensively remodelled. With regard to the revenues of the university, it is proposed to publish all accounts, including those of the press; to equalize fees, to confine the funds of the university to university purposes, and to remit the stamp duties on matriculation and degrees. The changes proposed in the constitution and government of the colleges, are equally extensive, and of much the same character. Time will not allow us to go into details, but they amount to the abolition of every unnecessary rule which may interfere with the true interests of the college. Among other points, we may instance the utilizing of fellowships by attaching professorial duties; the creation of scholarships tenable for a limited term, the opening of all foundations to the whole university, except in special cases; the election of heads of houses from the whole body of Masters of Arts; the regular and effective visitation of the colleges, with annual reports to the Crown, and the power of making and repealing statutes. But here we must stop. The commissioners, after carefully summing up their labours, add—"Of the proposals which affect the university, the most important are those which we have made for remodelling the constitution and for abolishing the existing monopoly of the colleges and halls, by allowing students to reside at Oxford without the expense of connexion with those bodies. In regard to the colleges, we would especially urge the immediate necessity of opening the fellowships and scholarships, of attaching professorships to certain colleges, of increasing the number and value of scholarships, of granting to the colleges the power of altering their statutes, and, above all, of prohibiting as unlawful the oaths to observe the statutes."

Those of our readers who cannot be brought to contemplate the evils of a bad system until they feel their practical effects, will probably ask what they have to do with Oxford, or even with University Reform? We have already told them that what applies to one of these Universities applies to all, and that Dublin must be the better of Oxford's amendment; and surely they will admit that a useful preliminary education, such as a well regulated College would afford, is a matter of importance to us all. These Universities grant Medical Degrees, which, although not legal licences to practise, are accepted as a qualification to do so, and if granted under vicious arrangements, must inflict most serious injury on our body. Everything, therefore, which promises to protect the medical profession against the operations of those who pervert educational institutions from their proper objects should be viewed with satisfaction. Many of our readers who recollect the flourishing state of the Medical School of Dublin five-and-twenty years ago, under the able and energetic management of Dr. MACARTNEY and his colleagues, now very naturally inquire how it has happened that in so short a time it has fallen into such a state of decay? Such a

question can be answered by such an inquiry only as this to which we are now alluding, and therefore is it that such comes to be of importance as regards medical affairs. If students come neither to attend the lectures nor to seek the degrees offered them in a great national institution, it is high time to ask those who govern that institution the cause of such an unexpected result. A consequence so significant must at once suggest doubts as to the whole policy of the government of any establishment where it occurs. Let the Board of Trinity College, and the Professors to whom the management of the Medical Department has been entrusted, be left to resolve a question of this kind, and it must remain unanswered; but if submitted to the test of discussion, a reply will soon be forthcoming. It will never occur to the minds of those who rely on what they rejoice to call the "University Principle," that this very principle of breeding-in-and-in has led to the lamentable results to which we allude; yet less partial inquirers might discover that it was owing to the exclusion from professorial chairs of all but those who have been bred in the institution, or of those who have had the good fortune to be sons or brothers of Fellows or pupils of Provosts and vice-Provosts. Let all institutions of this kind be "probed to the bottom" by the Dublin University Commission, and results much more valuable must follow than those to be expected from discreditable experiments and futile experiments.

#### REFORM IN THE BOOK TRADE.

It does not rain but it pours. Reform is the order of the day, the rule, and not as heretofore, the exception. Henceforth we may reasonably expect that when we buy books we may pay for them no more than they are worth, and if we write them, we may enjoy some share of the profits of their sale. But reformers must reform themselves if they hope to enjoy the fruits of reform. Book-makers must give value as well as book-publishers, and the matter must be as valuable as the print and paper. A little more German industry and research and a little more French originality and enterprise would greatly improve English medical literature if judiciously interwoven. Pondering on these things we begin to think that a few lending libraries of common modern medical publications in London and the large provincial towns might just now prove beneficial. Be this as it may, here is the result of the booksellers' strike:—

The bookselling controversy has received its *quietus*. Lord Campbell, in the name of himself and his colleagues, has delivered a judgment on the case before him which will suggest very few grounds for appeal. . . . Of course there could be but one decision in a controversy so transparent. With a few conventional compliments to the motives and conduct of the amalgamated publishers, Lord Campbell plainly pronounced that "the attempt to establish the exceptional nature of the commerce in books" had altogether failed; that the regulations of the association were "unreasonable and inexpedient;" that they ought to be maintained no longer, and that the Booksellers' Inquisition should be forthwith dissolved. It scarcely needed a formal analysis of such arguments as those of the association to convict them of utter unsoundness. There was a self-evident absurdity in the allegation that the sale of books could be diminished by a diminution in their price, and yet beyond this allegation the confederated publishers had really nothing to advance. Not only were their principles false, but their attempt was impracticable. They did not secure any uniformity in the price of books, they did not create any rapid distribution of new publications, but they did contrive to engender a great deal of ill-blood, and to manufacture such a system as ensured its own conviction as soon as it was exposed. . . . Beyond doubt, the joint producers of a book—the author and

publisher—may agree to fix whatever price they please on their manufacture, without respect to the costs actually incurred. If these costs amount in fair reckoning to 15s., the proprietors of the publication may settle its market price not only at one sovereign, but at five, or ten, if they so please. But what the reader should understand is, that this overplus charge, the division of which has been so controverted, is a charge imposed *after* all these arrangements have been made without any reference whatever to the property, so to speak, of the publication, and with a view to its distribution only. The author has no concern or participation in the matter at all. There is a particular price affixed to his work, which is so computed as to include his fair remuneration and all other ascertainable expenses of the production. Author and publisher provide their respective recompenses in determining this sum, and there is also a further and distinct provision for the publisher in respect of his strict and proper capacity of issuing or uttering the work. Now, to the "trade price" thus constituted an addition of 33 per cent. must be made to give the "publication price," and for the publisher to pretend that *this* price pertains to *him* is a monstrous wrong. He could only demand it by a most prodigious act of extortion against the public and an equal exercise of injustice towards the author. It is never taken into consideration in his reckonings with the author, but is always represented as an expense inseparable from the distribution of the book. To assume that the publisher would be entitled to this price in his own proper person, if he did not make "a reduction in favour" of the retailer, is utterly preposterous. His only justification for announcing at all a price so greatly beyond the remunerative figure is that he may have wherewithal to satisfy those whose remuneration must be cared for in addition to his own. He makes no "reduction in their favour at all." He retains every sixpence of the profit to which he is properly entitled, and merely gives them the benefit of a nominal assessment, which leaves a margin for their satisfaction over and above the consideration which they actually pay.

To Lord Campbell's plain recommendation of "entire freedom of transactions" between the two branches of trade, we would simply add the suggestion, that every publisher's concern with a book should terminate absolutely with its delivery, at the trade or author's price, to the retail dealer. In conclusion, we confidently hope that the discussion may be permanently advantageous to both writers and readers at large. Mr. Gladstone most truly said that the state of the bookselling trade was a disgrace to the community. Nothing in the markets of the universe is so extravagantly dear as a British made book, whether contrasted with other productions of labour at home or with similar productions abroad. With a large educated population, an inquisitive tone of society, and a general desire for knowledge, the most uncommon article of private purchase is a new book, and the commodity most certain to be procurable at a depreciated rate is a publication of credit and renown. The truth is that scarcely any degree of success can maintain prices so hugely artificial. When one-third of a book's nominal charge has been gratuitously added to its true cost, an appendage so preposterous is sure to be unsafe; and a collapse, which is merely the consequence of unnatural inflation, acquires the appearance of formal disparagement, to the prejudice of readers and writers together. Readers only get access to a publication when its conviction seems to have been pronounced; and writers, who see the price demanded from the public, and know the price accounted for to themselves, are scandalised and discouraged by the operation of an enormous charge combined with a miserable return.—*Times*.

### VALUE OF MEDICAL SERVICES.

I take the liberty to call your attention to an advertisement in the *Times*. The Royal Mail Steamer Company advertise for a cook, and offer the sum of £7 per month; they also want a pastrycook at £4 per month. This same company pay their surgeon £6 per month.

We wish that some ingenious correspondent would philosophize on this and tell why it is so. Is it that the Company know that if their passengers be badly fed they will warn other passengers not to become their customers, but that if they die nothing is said about it? Dead men tell no tales.

### MEDICAL UNION.

THE following reached us too late for the notice to which it is entitled. We propose, however, to return to it:—

Parsonstown, May 18, 1852.

SIR,—From the urgent solicitations of many influential members of the medical profession, we feel called upon to recommend that County Medical Associations should be established throughout Ireland as a preliminary step towards the formation of Provincial Associations, and, we trust, ultimately a complete organization of the medical profession.

We, therefore, request that you will convene a meeting of the medical men resident in the county —, and appoint a chairman, treasurer, and secretary, who shall act as deputies to represent the county, and assist in forming a provincial committee, or attend, when necessary, in Dublin at the general meetings of the profession.

It is of the utmost consequence that every exertion should be made to render this movement as general as possible, as we think that on the success of it will depend whether our profession shall assume that high position in society to which it is so eminently entitled, or that it shall continue, as it has too long been, powerless as a body, disunited, torn asunder by petty jealousies and disputes, unable to assert its rights, no matter from what quarter assailed.

Our present position is peculiarly critical and important. We have nothing to hope for but from our own efforts. By union, by effective organization, and the salutary influence of a central elective controlling body, we possess the power of protecting ourselves; and we would, therefore, earnestly entreat of you not to let the opportunity pass, but by a firm, temperate, and well-organized effort endeavour to wrest from the public that justice which has so long been withheld from us. —We remain your obedient servants,

WM. KINGSLEY, M.D., Chairman.

JOHN MORRISON, M.D., Treasurer,

JOHN WATERS, M.D., Hon. Secretary to the Association of Medical Officers of Dispensaries and Fever Hospitals.

To Local Secretary, county —

M. W. HANLON, M.B.

### MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The Annual Meeting of this Society will be held on Monday, the 7th day of June, in the College of Physicians, Grand Canal-street.

The President of the College will take the chair at four o'clock p.m.

Members of the Society are particularly requested to attend, and to prevail on non-subscribers to accompany them, that they may be made acquainted with the objects and operations of this invaluable institution.

By order,

W. KINGSLEY, } Hon. Secretaries.  
C. BENSON, }

May 18, 1852.

### THE ROYAL MEDICAL HALL, 64, DAME-STREET, DUBLIN.

 *Change of Proprietorship.*

### BEWLEY, OWEN, AND CO., APOTHECARIES, (LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of  
THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

### THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT embraces the SALE of EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

\* \* GENUINE COD-LIVER OIL,  
of the finest description.

*The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.*

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

*Superior Dissecting Instruments well worth the inspection of the Student.*

### THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention*; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

### THE ROYAL EXCHANGE ASSURANCE,

*Incorporated A.D. 1720, by Charter of George the First.*

THOMAS TROUTON, AGENT,

No. 8, WESTMORLAND-STREET, DUBLIN.

Fire and Marine Assurances on liberal terms.

Life Assurances with Bonus (which has averaged 43 per cent. on the Premium); or, at lower rates, without Bonus. Moderate Premiums and a fair division of Surplus.

Age.	With Profit.	Age.	Without Profit.
	£ s. d.		£ s. d.
20	2 0 11	20	1 17 6
30	2 11 7	30	2 7 8
40	3 6 3	40	3 1 9
50	4 11 3	50	4 5 8

Exemption by the Charter from the liabilities of Partnership.

The Security of a large Capital Stock, and the moral guarantee afforded by 131 years' experience and reputation.

The soundness of a thoroughly tested Office, with all the real improvements of modern practice.

THOMAS TROUTON, AGENT,

(Successor to Richard Purdy,)

No. 8, WESTMORLAND-STREET, DUBLIN.

### THE PHARMACEUTICAL JOURNAL, JUNE 1,

CONTAINING THE TRANSACTIONS OF THE PHARMACEUTICAL SOCIETY.

CONTENTS:—The Strychnia Panic—The Eleventh Anniversary of the Pharmaceutical Society: Report of the Council—Chinese Materia Medica—The Mackenzie Triturator—Liverpool Chemists' Association: On Smoke Burning; On Starches—Examination of Pavon's Collection of Peruvian Barks in the British Museum—Coccus Ilicis—Examination of Oil of Bitter Almonds—Materials for filling the Teeth—The Commercial Manufacture of Sulphate of Iron—Oxide of Zinc—Picric Acid—The Galbanum Plant—Bronze for Plaster Figures—Coffee Leaves—The Organic Acids—The Preparation of Carbonate of Amyl—Salicylic Acid—Anhydrous Acetic Acid—Chemical Memoranda, &c. &c. Price 1s.

London: John Churchill, Princes-street, Leicester-square; MacLachlan and Stewart, Edinburgh; and Fannin and Co., Dublin.

\* \* Volume XI. may be had in boards, as well as the preceding volumes, price 12s. 6d. each.

### WATERFORD UNION: WOODSTOWN DISPENSARY.

The Committee of Management of the Woodstown Dispensary District, in the Waterford Union, will, at a Meeting to be held at Rosduff, on Tuesday, the 8th day of June next, at Twelve o'clock, be prepared to receive Tenders from competent persons willing to undertake the duties of Medical Attendant to said Dispensary; and at One o'clock on same day the Committee will proceed to appoint such Medical Attendant at a salary of £100 per annum.

The candidates will be required to produce sufficient and satisfactory Testimonials of qualification and character. The necessary qualification and the duties to be performed are defined in the 16th and 17th articles of the General Rules issued by the Commissioners for the government of Dispensary Districts. The Board of Guardians have consented to allow £15 a year for Boardroom and Dispensary, provided the Medical Officer resides at Rosduff Cottage, which, with three acres and a half of land, can be had from the Proprietor at £30 per annum, free of poor-rates and taxes.

Further particulars may be learned on application to the Clerk of the Waterford Union, or the undersigned,

CHARLES COTTON, Hon. Sec.

### TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Twelve months, ... ..	£1 5 0
Six months, ... ..	13 0
Three months, ... ..	6 6

\* \* Orders to be addressed to Mr. HENRY BEAUMONT, 15, Molesworth-street.

Printed by Thomas Deery, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin.

London: John Churchill, 46, Princes-street, Soho.

## ON MENTAL PATHOLOGY.

### EXTRACT FROM AN ARTICLE ON CRIME, EDUCATION, AND INSANITY.

(From the Journal of Psychological Medicine.)

EVERY animal, whether human or bestial, is endowed with certain properties for self-preservation and self-generation; in the lower orders of creation these properties are called instinct; man, as an animal, enjoys an instinct too, but in him the instinctive faculties are associated with powers of a far higher quality, with a view to preparation for a nobler and an eternal state of existence.

His instinct, apart from these higher powers, resembles the instinct of any other animal in its essential properties. It is perfect from his birth; it is not progressive, because it is incapable of improvement. Instinct guides him to the breast; instinct dictates the squalling of the infant as well as the bleating of the lamb; instinct makes him shun pain, and cry for protection from approaching danger; the infant will shrink from a dog or a cat as soon as his eyes are capable of observation; he fears entering a field where cattle are feeding; he shrinks from the touch of strangers, and will even hide himself on their entrance; he runs to his mother at the howling of the storm or the pattering of the hail; all this fear is instinctive, and shared by the infant with the animal creation. As he advances to puberty, other instinctive feelings are awakened, and are indicated by the same change of manner, appearance, and disposition that mark the puberty of brutes.

But though his instinct is not progressive, those higher powers with which it is associated are; he is at an early age conscious of a will to obey or to resist his animal propensities; he cannot define this elective power, but he feels it; he is sensible of a freedom of action wholly independent of his animal nature; he marks the distinction between himself and dumb animals, not merely in outward form or in their respective objects of desire, but in volition. It may be restrained by circumstances, it may be fettered by parental authority; but still he feels and enjoys the will. This development of will in independence of necessity, is

the ray which opens the bud of reason; what may be its germ is known only to the Creator who planted it. As it expands, it exhibits faculties of calculation, of deduction, and of anticipation. He finds these faculties subservient to his animal wants, which instinct explains, though it can no longer provide the means of gratifying, and here the range of uninstructed reason closes. If we could conceive a man abandoned at this crisis to absolute solitude in the steppes of Tartary or the wilds of America, and destitute of all means of information from social intercourse, it is probable that he would degenerate into mere animal existence, though gifted with more cunning and less instinctive sagacity than the ourang-outang. He would indulge to satiety when food was abundant, but if sickness followed the indulgence, his rationality might prevail to check the repetition, till long privation provoked to a second surfeit; if the pain of sickness had been great, instinct would step in to restrain him, and reason would suggest reserving out of the abundance for a future meal; but whatever aid he might thus derive from reason in self-preservation, self would still remain the sole object of his thoughts, and animal indulgence the single end of all his efforts. In such a case reason would not become enfeebled, simply because she would be subjected to no struggle: subject to no law but that imposed by instinct for the preservation of the animal, she could violate no obligation; and the stronger she found the animal passions, the more imperative would be her duty to contrive for their gratification. She would probably become the slave of passion when conscious of no responsibility to any other master.

But the development of will not only gives its first bloom to the reasoning power, but informs the juvenile logician that there is imposed on his action an artificial constraint under the name of law; his will prompts him to the gratification of his instinctive wants; his reason suggests the means of gratification; and simultaneously with this newly acquired servant, he discovers that physical restraint impedes the freedom of his action, though not of his volition. First there is the law of the nursery; he resists and is sent to bed. Then there is the law of the school; he still

resists and is whipped. The law of the academy follows; he still resists and still is punished, restraint being throughout associated with disgrace. At length, emancipated from all physical control, he enters on the world at large, and there finds that a double code of law is enforced; the penalty of a breach of the one being corporal punishment combined with infamy; the breach of the other being visited by disgrace and exclusion from his caste. Where education has been based on religion, he finds a yet more formidable check, and yet more dreadful penalties, though more remote. Reason is thus exercised in early life by continued struggle, and gains strength by the conflict because she is assisted by physical and foreign discipline: while this continues she can do battle with volition and bring it into habitual subjection. The triumph tells to her advantage even on the score of gratification, for if less intense it is more certain in its occurrence and innocuous in its results. At length, however, this foreign aid is withdrawn, so far as regards immediate check; the penal consequences of indulgence to excess are removed to distance, and reason and passion are left in an open field to "fight it out" as best they may. The will desires to remove all impediments to gratification; the faculties of calculation, deduction, and foresight soon devise a way, but they at the same time distinguish danger in the distance, which instinct cannot see, and to which volition will not give credence. If these faculties, which we conventionally express by the term "reason," retain the power given to them by habit, volition remains in subjection still; if the force of habit is relaxed, volition regains her early ascendancy, and the animal predominates over the intellectual; this ascendancy is at first transient. It is a part of our animal nature, and mercifully ordained by the Creator, that pain, whether of mind or body, is only a present sensation; man cannot long exist under the pressure of unceasing pain; as physical causes will always produce their physical effect, pain will follow the first transgression of temperate limits; while the pain continues, reason condemns volition for its folly, and resolves to withhold further aid to its gratification. The pain subsides, and soon ceases to be recollected in all its acuteness, or even to be forgotten altogether. A first offence entails no permanent disgrace, and reason begins to urge that she has overrated the distress of punishment; she has undergone it once, and it is not so severe in recollection as it used to seem in anticipation; thus she is prepared to yield more readily on her next encounter with volition.

It is another general law of pathology that the second attacks of the same disease are, in their immediate and painful symptoms, less intense than the first, where the complaint is not, in its nature, chronic, or proceeding from constitutional affection; cases are constantly to be met with where the reiterated recurrence of a local disorder gives it an incurable hold upon the system, and yet the patient scarcely suffers pain amounting to inconvenience, though in its earliest stages the pain was acute.

Something of this kind obtains in excessive self-indulgence; smoking gives a familiar illustration; the first time that the fumes of tobacco are inhaled to even a moderate extent, most distressing sickness follows; the second time, if the interval is long, the same result will follow, but the nausea will be less and of shorter duration; after three or four experiments, this painful derangement of the stomach is no longer felt, unless the indulgence has been extreme; and eventually a man will smoke all day unconscious of any inconvenience. Many other morbid affections would admit of similar illustration, but for obvious reasons we forbear.

Reason, when defeated in her second conflict with volition, again suffers the penalty of pain, but in a less aggravated form; the effect of intemperance is the same in character but less in degree, and its recollection less admonitory, after every successive trial; the seeds of chronic disease and permanent debility are abundantly sown, but the painful paroxysms that at first were instant in their sequence, are no longer felt; thus the penalty, though still inevitable, is more remote, and reason, not sustained by immediate apprehension, is more and more enfeebled in her resistance.

We have thus far only described the struggle as it might obtain equally in the hypothetical case which we have put, of an utter outcast from society; a struggle between volition and reason, where pain is the only restrictive penalty, and we have adopted this simple form because it affords a plain view of its nature and progress. Though the laws of society interpose other restrictive penalties, and so far have strengthened reason for the conflict, the tactics of the warfare remain the same whether we place man in a social or solitary condition.

The inference which we are entitled to draw from these premises is, that it is exactly in proportion as self-control is rendered habitual by early training, that reason is enabled to retain her powers in health and strength through life. The force of habit must be added to the force of reason to keep the volition of the animal in constant, unvarying subjection. It must not be supposed that we overlook or depreciate those better motives that religion inculcates, or that all-powerful support which the sincere Christian derives from the grace of the Holy Spirit; we are considering the subject in the only light that befits a scientific journal; as connected with metaphysical inquiry into the structure of man as an intellectual animal, gifted with instinctive passion on the one hand, and with self-controlling faculties on the other, a free agent as regards his volition, yet restricted by physical and social responsibility as regards his acts.

Another objection which may be raised to our theory appears very plausible at its first enunciation. How does it occur that when the proportion of lunatics among the higher and middle classes is so large as 5000 to 18,800, or more than a fourth of the whole number, the proportion of criminals among the same classes is so extremely small as scarcely to amount to an appreciable quantity? It might be inferred that where so many are found incapable of subjecting their passions to reason, crime would abound among them to a much greater extent, if legal criminality and inordinate self-indulgence are identical in their origin, their progress, their objects, and their results; crime is, with rare exceptions, confined to the pauper class; lunacy, having regard to their relative numbers in the population of the country, is nearly twice as prevalent among their superiors; assuming that of the entire population in 1841, half a million will represent the higher and middle classes, it follows from the report of 1847, that their liability to insanity is in the proportion of 1 in 500, while the corresponding liability of the rest of the community is only 1 in 840; but the proportion of legal criminals is at least 100 to 1 against the pauper class. We have no data to estimate this latter proportion; it may more likely be 500 to 1, but it is enough ground for the objection to take the lowest estimate.

Instead of feeling it to be incongruous with our theory, we think the fact goes far to sustain it; we have already alluded to it in a former page, but only cursorily. It is almost a proverbial remark, that our laws are made for the poor and not for the rich; and there is necessarily truth in the remark, though not in the sense of vulgar declamation on the hustings. Food and warmth are the most pressing of our natural wants, as well as the most frequent in their occurrence; the cravings of appetite, whether in ourselves or in those who are dependent on us, must be satisfied at all hazards, and there is only an inferior degree of urgency in the necessity for clothing; hence the pauper is so often tempted to appropriate the property of others, not for excessive gratification, but for the indispensable nourishment of his animal nature and in strict obedience to animal instincts, that not only is legislation continually at work for the protection of property, but our judges, for the most part, reserve the severest penalties of the law for theft or fraud, visiting crimes against the person with comparative lenity. Every assize and every quarter sessions produces instances of transportation for felonies of this class, in absurd contrast with imprisonment for a few months for manslaughter, or assaults with intent, &c. The life of a man or the honour of a woman is often ludicrously weighed against a loaf or a yard of broad cloth in our scales of cri-

minal justice, and kick the beam; a child of seven years of age is, at the moment we are writing this, imprisoned in Knutsford jail on a charge of stealing a mug of the value of one penny! This extreme severity of the law and of the judicial caprice with which it is administered, not to mention the enormous expenses of prosecution, induce many to overlook the injury they sustain; and thus the pauper who begins by stealing to supply actual want, is emboldened by impunity to steal for gratification of his animal passions, ultra the necessity of his case; reason in vain points to consequences when experience proves impunity, and thus she loses all the aid of restrictive penalties in resisting the assaults of passion. We shall presently give a narrative pregnant with illustration of this, and shall have further occasion to advert to the same topic in considering remedial measures.

The higher and middle ranks of life are not exposed to similar temptation till a long career of extravagant indulgence has reduced them to actual want; even when their own resources fail them, the benevolence of friends, or more prosperous relatives, steps in to save them from actual destitution. Thus the insanity induced by intemperance will often overtake them before they violate any law but that which is imposed by the social code of decency. Even when reason is rapidly declining, she will retain sufficient restraining power to prevent a man incurring unnecessary hazard, when he can as easily obtain satiety of gratification without exposing himself to legal retribution. The loss of caste is also a restraining penalty, strongly operating in aid of reason among the higher orders, but it is unknown to the low-born pauper. Their sensual excesses, therefore, generally take a direction which entails no public ignominy. As for disgrace in their domestic circles, it is covered by affection, or, at the worst, retrievable by amendment; but whatever be the direction of a pauper's passions, if gratified at all, they must be gratified at the expense of others; hence, the penal law, though made alike for all, seems, by its almost exclusive application to himself, to be intended for him alone. Were the pauper criminal a man of wealth, he would become insane before he is marked a felon; but being a pauper, he becomes a felon before he is ripe for the asylum; abridgment of opportunity, and the discipline of a prison, preserve him in the incipient stage.

In confirmation of this view of the subject, it may be remarked, that in the comparatively few cases in which men in the higher walks of life become amenable to the law, it is usually found that it is for some of the offences that fall within the description of malicious violence to the person. When the passions of a malignant type are those habitually indulged, such as anger, jealousy, revenge, or the coarser sensualities, reason, though aided by all the restrictive-penalties of the social code, becomes subdued in his case as easily as in the lowest class; murder, and manslaughter in all its variety of guilt, violence to women, and even vindictive injuries to property, are crimes not confined to the pauper class; though far more frequent among them, simply, because reason has not been fortified by habits of self-control, and strengthened by education.

Nor is it less important to remark that, though in common with the rest of the world liable to other predisposing causes, the Society of Friends is exempt from intemperance as an inducement to insanity, and equally exempt from appearance in our criminal courts. Some spurious offsets of their body have now and then been arraigned, as, for example, Tawell; but it has always been found, on inquiry, that in these cases the dress had only been temporarily assumed, or the membership of very recent date. That mental powers and peculiarities are often transmitted from generation to generation, is undoubtedly true; but it would be extravagant to infer from this, any peculiar idiosyncrasy distinguishing the whole sect. In truth, those who have been admitted to terms of intimacy with them, a privilege which we have often enjoyed, know very well that, as a body, they yield to none in strength of passion, or generous warmth of feeling. Prudence, certainly, wears with them a severe aspect, but it is a self-controlling, not a freezing prudence. Where passion is right in

its direction, and noble in its object, no man will give the reins to it with more freedom than a calculating and prudential quaker.

And, to adopt the habitual phrase of one nearly allied to them, the late Sir Fowell Buxton, who was not less sound in his argument than resolute on his point, who never maintained a point where argument was wanting, nor wanted argument when the point was generous and good, "the sum of our argument is this,"—man, as an animal, is endowed with instinctive properties for self-preservation; but created for responsibility, volition is given to him that he may be a free agent, and certain faculties that we designate as "reason," are also given to guide his acts by reference to their consequences. His animal instincts impel him in a right direction, and his volition, partaking of animal instinct, carries him to excess; reason's function is to restrain volition in its tendency to excess, by the fear of penal consequences injurious to the animal nature. An unceasing conflict is thus maintained between two antagonistic powers. There can be no compromise between them; one or the other must succumb. If reason habitually triumph, she retains her seat till death; if she habitually yield, at last, she abdicates from debility and exhaustion. We have shown the identity of crime with insanity, in its progress, its objects, and its results. We have proved that intemperance, in its largest sense, is the predisposing cause of both, except in such lunacy as in its development betrays the acknowledged signs of local disease or organic malformation; and we have drawn this proof from statistics published by authority, or sanctioned by large medical experience.

## ON THE LATENCY OF CONTAGION.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—I feel it unnecessary to preface the following communication by a single remark, my only object being to record a fact bearing on a much-discussed question, "the period of latency of contagious and infectious diseases."—I am, &c,

RICHARD LONG, M.D.,

Medical Superintendent, Quarantine Port of Waterford.  
Arthurstown, June 4, 1852.

On the 12th of May, the emigrant ship "Crown," bound from Liverpool to New York, with upwards of 500 emigrants on board and no surgeon, was driven back to the anchorage at Passage East, having been at sea thirteen days, and suffered much damage from continued storm.

On going on board, I found two adults lying in confluent small-pox: these were immediately removed to hospital (one of them has died since), and such of the passengers as had means were permitted to take lodgings on shore whilst the ship was refitting.

On the 27th of May, my attention was called to one of them who had landed on the 13th, and had not been near the ship afterwards. He then presented all the ordinary symptoms of incipient fever of an inflammatory type.

On the 30th a copious eruption appeared which this day presented all the characteristic marks of well-formed small-pox pustules. This man has been vaccinated some years since, and his arm exhibits the usual pitting left by the vaccine vesicle.

## EXPERIMENTS ON THE DIET OF PRISONERS.

By ROBERT CHRISTISON, M.D., V.P.R.S.E.,  
Professor of Materia Medica in the University of Edinburgh.

In 1850 the General Board of Directors of Prisons in Scotland were induced by circumstances, which for brevity's sake may be here omitted, to make a series of observations, with the view of accurately ascertaining the effect of the prison diet on the bodily condition of the prisoners under their superintendence. These observations were conducted on a scale, and with a care, unequalled, so far as I know, by any investigation of the kind hitherto made public. The results appear valuable, alike in a practical point of view, and in relation to the physiology of nutrition. On this account, and because the numerical data were

entrusted to me for analysis, I have requested leave from the directors to make the results known; and they have kindly granted this permission.

The object of the inquiry was to ascertain, with every possible accuracy, whether the dietary of the regulations of the board was sufficient, and not more than sufficient, to maintain the health and condition of the prisoners. For this end, it was resolved to begin with those prisoners whose term of imprisonment varied between ten days and two months, and to judge from the results whether the same dietary might be made the subject of trial in circumstances of more doubt and nicety—viz., for prisoners sentenced to long terms of imprisonment. The observations were made on 896 males and 724 females, in the prisons of Edinburgh, Glasgow, Aberdeen, Dundee, Stirling, Paisley, Ayr, and the County Prison of Perth. Each prisoner was weighed at admission, and his state also noted as to health, strength, and condition. Similar observations were made once every fortnight afterwards, and finally just before liberation. To the data thus obtained were annexed the ages of the prisoners, together with any incident occurring in the course of the experiments, which might be thought to influence the numerical facts. During the progress of these observations, which were continued for three months, from 2nd December, 1850, till 2nd March, 1851, the prisoners were kept steadily on one dietary, differing slightly, however, in the different prisons. At the same time, the governors of the prisons were empowered to withdraw from experiment any individual whose health should appear to suffer sensibly from the diet.

The simple numerical facts, amounting to about 8000 observations on the weights of the prisoners, and as many on their apparent health, strength, and condition, were then put into the hands of Dr. MacLagan and myself for analysis, without any attempt on the part of the officers of the board or of the prisons to arrange or generalise them, the directors being anxious that we should investigate them without the possibility of a bias.

Taking the Edinburgh dietary as the dietetic basis in these experiments, it appears that the food of the prisoners consisted of oatmeal porridge and butter-milk at breakfast and supper, and broth and bread, or pea-soup and bread, at dinner. The broth, which was given five days a week, consisted of barley, vegetables, meat, salt, and pepper; the soup of pease and pease flour, with meat, salt, and pepper, and this was given twice a week. Supposing the broth and soup of each week to be distributed, so as to supply a uniform proportion of each on every day, the result is, that the average real daily nutriment of each prisoner was, in round numbers, seventeen ounces avoirdupois, of which four ounces were nitrogenous and thirteen carboniferous. By nutriment is here understood the sum of nutritive proximate principles in the dry state. No other estimate has any pretensions to accuracy.

To those who have made the dietaries for bodies of men a subject of scientific study, the allowance of nutriment indicated may appear small for a class of individuals, the greater proportion of whom are at the most active periods of life, and follow in prison some useful occupation. It contrasts strongly, for example, with the navy dietary for seamen, who have almost twice as much nutriment, and still more with that of harvest reapers in Scotland, who have nearly three times as much. Nevertheless, as the following facts will show, the prison dietary of Edinburgh is sufficient in the circumstances of the prisoners on whom these observations were made.

Thus, of 556 male and female prisoners in the prison of Edinburgh, 197 were found at their discharge to have maintained weight, 259 to have gained on an average two pounds and a quarter each, and 100 to have lost each on an average one pound and a half. Hence 82.0 per cent. had gained or maintained weight, and 18.0 per cent. had lost weight. The average loss was quite insignificant. The greatest loss sustained was five pounds in two instances, four pounds in three, and three pounds in one.

It is scarcely possible to have stronger evidence of the adequacy of a dietary, especially considering that not a

few people may lose a little weight with no great detriment.\* An equally satisfactory result is deduced from observations on the apparent health, strength, and condition of the prisoners. This is not so precise a criterion as the other for ascertaining slight differences, owing to the impossibility of using a fixed standard of comparison. On making the comparison as impartially as possible, however, it appeared that not a single prisoner of the 556 had lost in apparent health and condition; and that 110 of them, or almost 20 per cent., had manifestly improved in these respects. It is worthy of remark, that in the latter category there were 17 who had lost each a pound and a half on an average, and that one of these lost three, and another four pounds.

The result of this section of the observations is altogether so favourable, that, so far from any fear arising lest the dietary of the Edinburgh prison should prove defective in nutriment, a suspicion might very naturally be excited, that it may be rather redundant in that respect. I believe this suspicion was actually entertained in some quarters; but I do not know on what grounds. That is was really groundless—and that practical experience had taught the authorities the precise limit to which the nutriment might be reduced consistently with the preservation of health and condition—will sufficiently appear from what follows.

In the prison of Glasgow the amount and quality of the nutriment in the diet was almost precisely the same as in the prison of Edinburgh. The details were somewhat different, inasmuch as barley-milk, made of pearl-barley and skimmed milk, was substituted for broth on one day every week, and cheese for pea-soup on another day. But the analysis of an average day's dietary shows that the nutriment was all but identical, the nitrogenous ingredients being 4.06 ounces, the carboniferous 12.58, and the total nutriment 16.64 ounces.

*Nutriment in the Glasgow Prison Dietary.*

	Rough Weight.	Nitrogenous Nutriment.	Carboniferous Nutriment.
Oatmeal.....	8.86 oz.	1.20 oz.	6.23 oz.
Butter-milk.....	22.14 „	1.33 „	0.44 „
Bread.....	7.71 „	0.52 „	3.75 „
Meat.....	0.71 „	0.16 „	0.10 „
Barley.....	1.71 „	0.24 „	1.16 „
Peas.....	0.91 „	0.21 „	0.54 „
Skimmed-milk.	4.00 „	0.18 „	0.22 „
Cheese.....	0.30 „	0.20 „	0.00 „
Vegetables.....	1.45 „	0.02 „	0.14 „
Total daily nutriment,		4.06 „	12.58 „

Although the results of this dietary were satisfactory, they were not so entirely favourable as in the prison of Edinburgh. Of 549 male and female prisoners in Glasgow, 299 gained, 71 maintained, and 179 lost weight. That is, 67.3 per cent. had improved or remained stationary, and 32.66 per cent. fell off. The average diminution of weight was also greater than at Edinburgh, being nearly four pounds for each prisoner; and 15 of them lost so much as 7.25 pounds each. Farther, the state of the prisoners as

\* Although it is true that some people in a state of health may lose weight considerably without injury to their health, and that probably most persons may lose a little without any material harm, this is no objection, as some contend, to the test of loss of weight, applied on a large scale—especially to persons of the class of prisoners—being taken as evidence of a dietary being inadequate. All observation tends to show, that, when a large proportion of a body of men lose sensibly in weight, ill health is at no great distance; that their bodily strength is impaired; that they will soon become comparatively unable to grapple with the exciting causes of disease; and that, in the end, diarrhoea and scurvy are apt to be engendered among them, if the defective diet be long continued.

to apparent health, strength, and condition, was likewise conformable. For four individuals had evidently suffered in these respects, and only 13 per cent., instead of 20, as in Edinburgh, had improved.

Results remarkably similar to these may be deduced from observations made at the prisons of Aberdeen and Stirling. In these two prisons the diet was at least equal in nutriment to that of Edinburgh. Without going into greater details, it may be sufficient to mention, that the average daily allowances in a week's dietary contained in Aberdeen, 3.98 ounces of nitrogenous, 13.03 carboniferous, and 17.0 total nutriment; and in Stirling, 4.27 nitrogenous, 13.4 carboniferous, and 17.67 total nutriment. The effect on the prisoners was as follows:—Of 143 male and female prisoners in both prisons, 71 gained, 26 maintained, and 46 lost weight,—that is, 68 per cent. either maintained or gained weight, and 32 per cent. lost in that respect. The average diminution among the latter was 4.2 pounds each, and 8 of the 46 lost each on an average 9.5 pounds. The number who improved in apparent health and condition was 14, or 9.75 per cent.; and those who fell off in these respects, were 5, or 3.5 per cent.

The results thus supplied from the prisons of Glasgow, Aberdeen, and Stirling are in themselves satisfactory. Still they are not so favourable as those obtained with the same diet at Edinburgh. They raise a suspicion, that in Glasgow, Aberdeen, and Stirling, there was some adverse cause which made the same diet less perfectly nourishing than in Edinburgh. Sundry conjectures might be formed as to what the cause may be. Since none of these conjectures can be tested with the information at present existing, I shall leave the question here unconsidered. But, as the general health and condition of the prisoners in all the three prisons must be admitted to have been satisfactory, it is a reasonable presumption that the moderate loss of weight in so many as a third part of the whole 692 prisoners was owing to some slight defect in the adjustment of the diet to their particular circumstances.

If this conclusion be correct, it will follow that the dietary of the Edinburgh prison, which I set out with assuming as the dietetic type for these experiments, is not too redundant in nutritiveness, since it proved not entirely sufficient in some difference of circumstances so minute or obscure as to be inappreciable with present information.

It certainly proved to be insufficient in another of the prisons, where the circumstance that made it so was not far removed from view. In the prison of Ayr, of 42 male and female prisoners, only 12, or 29 per cent., gained or maintained weight; while the large proportion of 30, or 71 per cent., lost weight. The loss sustained by each of the 30 was five pounds, on an average, in 6 of them the average loss was 9 pounds, and in 5 the governor of the prison found it necessary to increase the allowance of food. Nevertheless, the nutritive value of the diet in the Ayr prison was quite as high as in that of Edinburgh. The prisoners had skimmed-milk instead of butter-milk at breakfast and supper, and barley-milk instead of broth on two days of the week. The average daily food in consequence contained, 4.17 ounces of nitrogenous, 13.06 carboniferous, and 17.37 total nutriment.

It is easy to understand why this dietary was insufficient in the particular circumstances. For a large proportion of the prisoners, unlike those of Edinburgh, Glasgow, Aberdeen, and Stirling, were agricultural labourers—muscular, bulky men—accustomed to much exercise, and a liberal supply of ordinary labourer's food. This circumstance was pointed out as the probable cause by the governor of the prison, and it is evidently sufficient to account for the result.

If farther evidence were wanting to prove that the standard diet used in these experiments was not unnecessarily nutritive, it may be found in the following singular facts:—The prisons of Dundee, Perth, and Paisley were circumstanced in all ordinary respects, but one, like those of Edinburgh, Glasgow, and Aberdeen. The prisoners were of the same denomination; their employment in prison was much the same, their regimen in other respects

was also much the same. But nevertheless the result of the observations on their weight and general condition is very different. Summing up the data from the three prisons conjunctly, since they lead to nearly the same numerical results in each, it appears, that, of 330 prisoners, 165, or exactly 50 per cent., maintained or gained weight, and the same number and percentage lost weight to the amount of 4.3 pounds each on an average. Of those who lost, there were 23 in whom the average diminution was 7.75 pounds. In point of health, strength, and general condition only 49, or 15 per cent., are stated to have improved; while 14, or 4.2 per cent., manifestly fell off.

The only circumstance which can be discovered to account for the inferior condition of the inmates in these three prisons, was an inferiority in the quality of their nutriment. This inferiority is not manifest to ordinary practical observation, otherwise it would have been corrected. But it can be irrefragably proved by a scientific analysis of the dietaries.

By a regulation for adjusting the prison dietaries, treacle-water might be substituted by the governors for milk at breakfast and supper. This equivalent had been introduced some years ago on authority which was supposed to justify its adoption. But the substitution often occasioned discontent among the prisoners, and sometimes embarrassment to the board and other prison authorities; and not without reason, because treacle, a purely carboniferous article of nutriment, can be no true equivalent for milk, which abounds in nitrogenous matter.\* Taking the Dundee dietary as an example, it was found by analytic reduction to be constituted so that the average daily allowances contain, in round numbers, 2½ ounces of nitrogenous nutriment, 14 ounces of carboniferous nutriment, and in all 16½ ounces; so that the total nutriment is the same as in the dietary which answered so well in Edinburgh, Glasgow, and Aberdeen; but the nitrogenous nutriment, which supplies the necessary repair for the constant waste of the tissues, was less than in that dietary in the ratio of very nearly two to three. This is a most material reduction. No very evident effect, indeed, resulted to the health of the prisoners. But an injurious effect could not fail to ensue under a more prolonged use of such a dietary.

It is a singular circumstance, which adds to the confidence felt in the scientific method of investigating such a subject, that the average loss of weight sustained by the prisoners in Dundee, is closely accounted for by this deficiency in nitrogenous nutriment. The Edinburgh dietary contains 28 ounces weekly of nitrogenous nutriment. The Dundee dietary contains 9 ounces less. In the course of eight weeks the difference will amount to about 4½ pounds: the actual loss was 5½ pounds.

Having proceeded thus far in the inquiry, it occurred to me that I was now in a condition to ascertain whether the common notion is correct, that, in at least the working classes of the community, the amount of food required for maintaining the health, strength, and condition of the body, is much the same for both sexes, for all periods of life between puberty and old age, and for individuals of all ordinary weights or sizes. This notion is scarcely founded in physiological probability; but it is invariably acted on in regulating the dietaries of bodies of men.

If it be true, we should find, that, when a dietary is very nicely adjusted for the generality of a body of men, as appears to have been the case for the prisoners in Edinburgh, Glasgow, Stirling, and Aberdeen, the adjustment will be found equally correct for all denominations. If, on the contrary, the notion be false, the error will stand forth in such numerical observations as were made in the present inquiry.

\* An extraordinary blunder is often committed by practical men in regulating dietaries, or writing about them, when they overlook milk as a source of nutriment, misled, probably, by its being a liquid. It becomes a solid aliment in the stomach by coagulation, and contains from eight to fourteen per cent. of real nutriment, of which about a third is nitrogenous. Fine qualities of it actually contain not much less than a half of the nutriment in beef and mutton.

First, then, as to the two sexes, it appears that in Edinburgh prison, of 273 males 72 lost weight, and of 283 females only 28; that is, 26.3 per cent. of the males, and only 10 per cent. of the females. In Glasgow, of 309 males 127 lost weight, and of 240 females only 52; that is, 41 per cent. of the former, and 21.7 of the latter. The difference in Aberdeen prison is not so great. Of 55 males 21 lost weight, and of 30 females 9; that is, 38.2 per cent. of the former, and 30 per cent. of the latter.

Next, as to the bulk of the prisoners, I have compared together those males who weighed less than 150 pounds with those who weighed that much or more, and with the following results:—In Edinburgh, 210 male prisoners weighed less than 150 pounds, and 63 at least reached that standard. In Glasgow, the numbers were 258 and 51; in Aberdeen, 40 and 15. In Edinburgh, the percentage of the lighter denomination who lost weight was 23.3; but of the heavier 36.5. In Glasgow, the percentages were respectively 38.7 and 53.0; and in Aberdeen, 30 and 60.

Lastly as to age, it seems reasonable to infer, that growing lads, between 16 and 20, must require more nutriment than those who have attained maturity; because their bodies must be not only maintained, but likewise enlarged. Placed on a uniform diet, therefore, if that diet be very nicely adjusted for the generality, the former may suffer when the latter do not, or in a less degree. In Edinburgh prison a perceptible difference was shown. Of 80 male prisoners between 16 and 20, inclusive, 31.2 per cent. lost each on an average a pound and a half in weight; while among those above 20, the percentage was 24.3. In Glasgow, the difference was somewhat greater. Of 88 growing lads, 53.4 per cent. lost in weight at the rate of four pounds and a half each; but males above 20, lost weight only in the proportion of 36.2 per cent. In Aberdeen, the number who lost were proportionally almost the same in both denominations; but the prisoners of each class were rather few to yield safe results.

The following conclusions may be drawn from the preceding statements:—1. For the average of people whose occupation involves moderate muscular effort and no great exercise, a simple, well-selected sort of food, supplying seventeen ounces of daily real nutriment, of which four ounces are nitrogenous principles, constitutes a sufficient diet for maintaining health, strength, weight, and general condition; but less is not sufficient. 2. The proportion of nitrogenous nutriment in such a diet cannot be very sensibly reduced below four ounces a day without risk of injury. 3. This amount of nutriment, though in general adequate for the average in the supposed circumstances, is not always so. 4. It is probably inadequate for those who have been accustomed to a vigorous occupation in the open air, and a liberal dietary, even when their employment is changed for one involving no great muscular effort or exercise. 5. It is inadequate for a fair proportion of persons considerably exceeding the average in bulk. 6. It is inadequate for a considerable proportion of growing lads between 16 and 20. 7. It is more generally adequate for females than for males. 8. It is rendered occasionally inadequate by other causes not distinctly indicated by the observations in the Scottish prisons, but certainly independent of any increase in habitual muscular exertion. 9. Hence the economical regulation of the diet of bodies of men must always be a matter of great difficulty; and if deviations from the standard dietary be not allowed with a liberal discretion, injury will be apt to ensue. And here it should be added from other observations, that suspicion may be lulled by no very perceptible injury except loss of weight occurring in ordinary seasons; while, nevertheless, manifest injury will arise in periods of epidemic disease. 10. The prison dietary in Scotland has been very successfully adjusted by long experience in most of the prisons, so far as regards the class of prisoners who formed the subject of the preceding observations and experiments: viz., those imprisoned for terms not exceeding two months. But in that dietary treacle-water cannot be substituted for milk without a reduction of flesh, the forerunner of probable ill health, unless some compensation be made in other

articles of food. It has, in fact, been disallowed by the board since these experiments were made. 11. In adjusting dietaries, and in all practical inquiries into the subject, reliance ought never to be put in practical observation alone; but scientific analysis should be likewise brought into requisition. I could quote numberless errors committed by merely practical men, which could scarcely have escaped notice had they united scientific knowledge to practical skill. Let me conclude with one only, which happened lately near the fountain head of knowledge on this subject.

It appears from the Report of the Inspector of Prisons in Scotland for 1851, that the condition of the prisoners in Carlisle jail was far from satisfactory during the previous year. Of 68 persons only 9 had gained or maintained weight; and 59, or almost 87 per cent., had lost on an average 6 pounds and a half each. This is worse than even what has been noticed above as to Ayr prison; where it was judiciously thought advisable to discontinue the experiments in several instances. The inspector expresses his surprise at the result, and, in adding the dietary in an appendix, makes no commentary upon it. Consequently it would appear that he did not suspect the cause to lie there. Yet by scientific analysis nothing can be more clear than that the diet was faulty.

The Carlisle dietary presents ten different scales for the several denominations of prisoners. The class of prisoners coming nearest those who were made the subject of observation in the Scottish prisons, comprises "prisoners at hard labour for terms exceeding two weeks, but not exceeding six weeks, and those not at hard labour but confined for terms between two weeks and three months." From the following analysis of their average daily food, it appeared that these prisoners received only 2.5 ounces of nitrogenous, and 11.16 carboniferous nutriment, or 13.66 ounces in all.

Resting on this principle, it will be seen that there is no encouragement in the results of the observations upon prisoners in Scotland confined for terms within two months, to extend the experiments with the same diet to those imprisoned for longer terms. This was an object held in view by the Board of Directors. But the dietary being found just sufficient, and no more, for the former class, and in some circumstances insufficient even for them, the effect of applying the same diet to prisoners confined for long terms may be pretty confidently predicted as likely to prove unfavourable. With due and obvious precautions, the experiment might be tried with perfect safety, but with very small chance of a satisfactory result. Other incidents in the late history of these prisons lead to the same conclusion; but they could not be noticed here without disproportionate details. I may recur to them hereafter. For the present it is better to confine myself to the deductions which may be drawn from the observations lately made in the Scottish prisons.—*Monthly Jour. of Med. Sci.*

#### ADDITIONAL REMARKS UPON THE VALUE OF VERATRUM VIRIDE.

By W. C. NORWOOD, M.D., of Cokesbury, U.S.

WE have been endeavouring for some time to awaken and interest the profession in the powers and properties of veratrum viride. We now venture again, and the third time, to call aloud. We have been cautiously and, as we believe, judiciously using the above article, alone and in various combinations, for eight years—which ought to allow us to speak with some confidence, and should be a reasonable warrant for what we may assert in the sequel. After various trials and combinations, we unhesitatingly assert that we verily believe we have adopted that form of combination which is the best. We gave to the public in two former numbers, a portion of our experience, with a statement of what were the powers and properties of the article, and we give this in further addition. Its powers are perhaps more strikingly manifested in the speed and certainty with which it relieves and cures pneumonitis typhoides. Its culminating curative powers stand out in

all probability more strikingly in this than in any other disease. We fearlessly assert, that it is as much of a specific in pneumonitis as quinine is in the treatment of intermittent fever, and that it will cut short and break up at the first outset of the attack, in as many cases (due allowance being made for the violence of the attack and the importance of the organs affected) as quinine will of intermittent. We challenge the world to produce its equal, either singly or in any combination of remedies. Again: it is the sheet-anchor in typhus and in typhoid fevers. It is the only remedy that has ever been found to arrest the above fever or fevers, and to rob them of the terror and dismay they are known so universally to produce. It not only cures cases beyond the reach of any known remedies, in the last stage of the disease, but it breaks up many cases at the outset, and cuts short others that are fully formed, and in full and perfect progress. Further: we have found nothing that arrests convulsions in children, accompanied with high febrile symptoms, from one year old and upwards, with anything approximating such certainty and speed. In whooping-cough it stands unrivalled and alone, as a remedy that may be relied on when accompanied with high febrile excitement. Dr. Stewart says: "I know of no remedy worth mentioning save yours. Having seen cases of pertussis every day for ten months, and used your remedy every few days, I cannot recommend it to that notice it deserves without being considered as an enthusiast in its use." We hasten on to notice further, that it is a powerful and reliable agent in the treatment of typhoid dysentery: that with it we can readily manage that fearful, malignant, and mortal disease.

The next class of diseases we shall notice, and briefly illustrate its powers in, by a couple of cases, is the certainty and speed (we mean undoubted certainty) with which it cures or relieves the pain and febrile excitement occasioned in mumps by a metastasis to the testicle.

**Case 1.**—Mr. A.—Found him with the testicle much swelled, and intensely painful; great pain in the head; skin hot and dry; pulse 110; tongue thickly coated. Commenced with eight drops every three hours, the dose to be increased one drop every portion till nausea or vomiting occurred. The third portion excited free emesis; the pulse was reduced to 65; the skin became cool and moist, and there was perfect relief of the pain, and all unpleasant febrile symptoms were subdued and removed, and by continuing the remedy in small portions, so as not to sicken, there was no return of either pain or febrile symptoms.

**Case 2.**—Mr. S.—The symptoms were similar to those of the first case, being free from pain in the head excepted. He was treated in the same manner precisely. The third or fourth portion vomited freely, on the occurrence of which the pulse was reduced to 60, which before was upwards of 110; with an entire removal of all pain and febrile excitement.

In traumatic lesions we have tested its powers sufficiently to warrant us in asserting that it will control and regulate any arterial excitement produced thereby. We fully tested that fact in the New York Emigrants' Hospital, and can calculate its value and importance by the ease and certainty with which it controls and subdues high arterial excitement after capital operations. How many cases run down and perish from high sanguineous excitement alone, without any other appreciable cause, after well executed operations? We feel confident that in the above we can afford the surgeon a remedy that will quiet his fears and remove his apprehensions in such cases, and that he can control at will inflammation, arterial and general sanguineous excitement, that so often supervene and defeat the successful result of the most skilfully executed operations in surgery.

We feel fully assured that we can confidently offer to the world the desideratum so long sought and wished for—namely, an agent that will certainly and undoubtedly control and subdue morbid arterial excitement, the great frequency of the contractions of the heart and arteries, so especially belonging to all acute diseases, and the removal

of which has been as difficult as its presence was universal in all severely acute diseases. Dr. Bass, writing on the subject, observes:—"It seems to act directly upon the heart and arteries, as manifested by a diminution of the force and frequency of the pulse; it relieves irritation, congestion, and inflammation; establishes the equilibrium of the circulation; excites free diaphoresis and expectoration, which well adapts it for the treatment of pneumonitis, pneumonia typhoides, and asthma; in which diseases I have used it effectually; or in other words, with unparalleled success." Dr. J. Branch, in writing to us on the same subject, states:—"I will simply say, I regard it as one of the most important articles of the materia medica. You never made a more just and appropriate remark than you did when you said, it would say to the pulse, 'thus fast shalt thou beat and no faster.' I have used it in many cases of the severest sort of typhoid fever with the happiest effect. It will cool the surface, reduce the frequency of the pulse, while, at the same time, it does not diminish its volume or strength. Indeed, I have sometimes thought that the volume and strength of the pulse was increased in atonic cases under the use of this article. The following will serve as an illustration of its use and effects:—When called to a case of typhoid fever, with a hot surface, frequent pulse, great restlessness, in a word, with all the symptoms of such a case, if the patient be an adult, I commence with giving him eight drops of the article every two hours, and increase the dose a drop or two at every succeeding dose, until slight nausea is produced, never fearing but that when this effect is produced I shall have a cool surface, an infrequent pulse, and an absence of all febrile excitement. I then continue more or less of the article until the case is broken up."

Dr. Stewart, in a letter on the same subject, writes thus:—"I do not believe any remedy or combination of remedies possesses the same powers in pneumonia or pleuritis as yours; it not only lessens the frequency of the pulse, but exerts a curative influence on the disease; and with regard to its lessening the frequency of the pulse, I unhesitatingly say, without fear of successful controversy, that it will control the pulse in any and every case where it is morbidly excited. I regard your remedy as peculiarly adapted to the treatment of pneumonitis, pleuritis, pneumonia, typhoides, pertussis, typhus fever, with increased action of the heart and arteries. Mr. Rogers, in whose family you practise, was attacked with typhoid pneumonia about the time you left home, and Drs. Agnew and Traynham attended him, and when all hope of his recovery was lost, his family recollected that some of them had been rescued from an untimely grave by your remedy, urged the physicians to give the drops. Neither of the physicians having the medicine, they determined to send to me for it; and with only two drachms of the tincture, both of the physicians assured me they had saved Mr. Rogers, and would not take less than five dollars for the remnant of the two drachms."

We have every confidence that it will cure scarlet fever; also, that it will be a valuable remedy in puerperal fever. If we should succeed in curing yellow fever, or materially lessening its fearful mortality, who will not hail it the master discovery of the age!

We challenge the world to discredit the above. We pledge ourselves, and stand ready to demonstrate the powers and effects claimed. We have staked our reputation for veracity and medical skill on the above, and we are perfectly willing to abide the verdict of a liberal and enlightened profession, and an intelligent community. Truth is omnipotent. The above was not got up in a day, or a corner, but is the result of years of laborious investigation, and of time and money spent to prove and test the certainty and correctness of our experience, and the conclusions reached. The world can either receive or reject it.\*—*Southern Med. and Sur. Jour.*

\* The preparation of veratrum viride used by Dr. Norwood is the saturated tincture of the root, and if a tithe of what is claimed in this article be true, the remedy deserves the attention of practitioners.—*Ed. Buffalo Journal.*

## ON FRACTURES OF THE LOWER END OF THE RADIUS.

By H. BOND, M.D., of Philadelphia.

I PROPOSE to examine the mode of treating these fractures, as now commonly practised in our hospitals, and as taught by the most recent American and English authors. It is unnecessary to state in detail to the members of this college what this practice is. I may briefly say that it consists in the use of two long straight splints, with compresses or cushions and bandages. The palmar splint extends from the elbow down to the extremities of the fingers. Some, however, do not allow this to extend below the second joints of the fingers. The dorsal splint extends sometimes only to the extremity of the metacarpe. When this dressing is applied, the longitudinal axis of the forearm will be continuous or parallel with that of the hand.

There are several objections to this mode of dressing the fracture which I will attempt to point out. In the first place, it violates what ought to be regarded as a surgical canon in the treatment of fractures—viz., to adopt such a position as will put all the muscles, acting on the part, as much in repose, as free from tension, as possible, so that the least counteracting force will be required. 2nd. The constrained position of the hand demands tighter bandaging, in order to prevent derangement of the fragments by paralyzing or subduing the muscles that are rendered tense by the position assumed. 3rd. This constrained position and tight bandaging greatly increase the danger of that protracted or permanent rigidity of the hands and fingers which is a too frequent result of those injuries. 4th. This mode of dressing by long straight splints not only increases the danger that it will result in rigidity, but that when it does occur, the hand will be left unsightly, inconvenient, or useless. 5th. There is another objection to it which will be regarded by the surgeon as of more or less importance, according as he is actuated more or less by the feelings of humanity. I refer to the distress or discomfort which must result from a constrained position and the force applied to maintain it.

The muscles that act on the hand are least tense, or most in repose, when the hand is inclined backwards, so that the metacarpe forms a considerable angle with the forearm, when it is also inclined inwards towards the ulnar side of the arm, and when the fingers are moderately flexed. In this case it will be perceived that the longitudinal axis of the forearm, if prolonged, would not correspond with that of the hand, but would pass through or very near the point, where the thumb and index finger most easily and naturally meet. Thus in the innumerable manipulations with the thumb and fingers (as with a pen, pencil, button, needle, money, &c.), their points most easily and naturally meet in this axis of the forearm. This will be found to be the position of the hand, when it hangs by the side with all the muscles relaxed.

This consideration is of little comparative importance in the case of young persons, and of those who have followed no laborious handicraft; but to persons advanced in life, and to those whose muscles and joints have become rigid by hard labour, and to whom the hand is the means of subsistence, it is a point of very material importance. A large portion of these fractures occur among such patients. When such a hand is firmly swathed by a roller upon the long straight palmar splint, it is forced into a constrained position, and some of the muscles, acting on the fragments, are put into extreme tension. This condition of the muscles must act strongly on the fragments of the radius, and must tend strongly to derange them, especially when the fracture is oblique.

To counteract this tendency to displacement of the fragments on account of the tense condition of the muscles, the bandage with the compresses must be applied so tightly as greatly to increase the risk of that frequent ill-success so well described by Dr. Barton. When the hand is placed in the position above described, so as to take off tension from all the muscles, there will be so little tendency to displacement of the fragments that a very gentle pressure

of compresses and bandages will be adequate to maintain them in their proper relation to each other. The dressing may be removed earlier, so as to give motion to the hand and fingers without danger of producing derangement of the fragments, and the gentle pressure of the dressing will be less likely to deprive the tendons and sheaths of their lubricity, and thus to cause permanent adhesions.

There are cases, as before observed, where such violence is done to the bones and soft parts, especially in elderly persons of a rheumatic or gouty diathesis, that it may be impossible to avoid permanent adhesions and rigidity. In such cases, if the usual authorized mode of treatment be adopted, the result will be a most awkward, unsightly, useless member. But if the hand can be placed and retained in the unconstrained natural position above mentioned (to say nothing of the better chance of escaping permanent stiffness), in the first place, the unsightly deformity will be avoided; and in the next place, the hand will not entirely have lost its use. For the hand, thumb, and fingers being placed very nearly in the position of their most frequent uses, the interossei, the lumbricales, and the several short muscles of the thumb will, by causing only a very limited motion, enable the hand to perform very many of its useful functions.

I can say with confidence, not only from *a priori* reasoning, but from some experience within the last few years, that the dressing of a limb on the principles here inculcated will very materially conduce to the comfort of a patient. I shall here make no comment upon what is said about paralyzing the muscles by tight bandages, nor upon the power of the body to accommodate itself, by a very painful discipline, to very distressing necessities.

The importance of the position of the hand in the treatment of fractures of the radius has been fully recognized for a long time by eminent surgeons. In these cases, Mr. Cline did not allow the splints or the sling to extend below the wrist. His object was to let the hand, by its own weight, and without any impediment, incline towards the ulnar edge of the forearm; and while the ulna acted as a counter-extending force, this inclination of the hand would prevent the fragments from over-riding or overlapping each other, and make it very easy to keep them in apposition. He understood well the mechanism of this accident. When the radius alone is broken, the ulna affords all requisite counter-extension, and in proportion as the hand is inclined towards the ulna will the lower fragments be drawn down, so that there will be hardly a chance for one fragment to overlap the other; certainly there will be little difficulty in keeping the fragments in apposition with very gentle means. But Mr. Cline's method of dressing, in order to accomplish the indication, was too indeterminate; he could not depend upon maintaining steadily the same degree of inclination of the hand, and one might suppose that there would be danger of producing artificial joints. Nevertheless, I am persuaded that, with Mr. Cline's method of treatment with short splints, there would be fewer cases terminating in deformity and loss of the use of the hand, than when the arm and hand are tightly swathed in long straight splints.

Sir Charles Bell long ago inculcated the importance of the inclination of the hand in the treatment of fractures of the forearm, and he has given a plate illustrating his opinion. Boyer is very explicit upon this point. He says, "the extension should be made by inclining the hand towards the ulnar edge of the forearm." Yet this obvious principle and this explicit direction are wholly disregarded in the present usual mode of dressing with long straight splints and tight bandages. Dupuytren, whose lectures on this subject should be studied by every surgeon, devised a splint—his *attelle cubitale*—with the special object of maintaining this inclination of the hand towards the ulna. Notwithstanding this great man devoted such deep attention to this subject, there were serious defects in his apparatus, which have been pointed out by subsequent French writers. I have attempted to devise a mode of dressing these fractures, having reference to the principles advanced in this paper, and that will meet the following indications:—1. To

maintain such an inclination of the hand upon the forearm as shall most effectually relieve the muscles from tension or put them in repose. 2. To maintain the hand and fingers in a position that, if rigidity should result, the member shall be as little an incumbrance, and retain as many of its uses as possible. 3. To make it easy of application, requiring no extraordinary skill or dexterity, and little liable to be deranged or displaced. 4. To make the dressing easy and comfortable to the patient, while it does not lack efficiency. My own experience of its use within the last three years convinces me that I have to some extent accomplished these indications. How far this shall be corroborated by others can be known only when others shall have had time, opportunity, and disposition to test it.—*Phil. Med. Examiner.*

### ON HÆMOPTYSIS.

By DR. THEOPHILUS THOMPSON, F.R.S.

ALTHOUGH great alarm is generally evinced, and danger of sudden death feared, when this symptom is considerable, yet it appears in reality that such is very rarely the case, for there are two circumstances in reference to the circulation in phthisical lungs unfavourable to the occurrence of profuse hæmorrhage. In inflamed lung, the bloodvessels, though tortuous, are free, but in tubercular lungs the blood coagulates in the extremity of the vessels. But there is an additional point well worthy of your attention. When you look at this large vomica you observe a considerable band passing across it. Of what does this band consist? It contains no bronchial tube. Bronchial tubes readily ulcerate; and by that process expectoration from cavities is promoted. The band consists mainly of bloodvessels and cellular substance. Bloodvessels are inapt to ulcerate. The walls of the pulmonary arteries, when surrounded by tubercular ulcerations, instead of sharing the disorganization, usually thicken; by the deposition of fresh material their calibre gradually lessens; after a time they cease to be pervious; they are filled with a thin, reddish, fibrinous plug, and transformed into solid chords.

It is probably only in those rare instances in which such a vessel is suddenly torn before the calibre is perfectly closed, that fatal hæmorrhage is at all likely to occur. The popular idea that all bleeding from the lungs is produced by ruptured bloodvessels is a serious error. The ordinary cause of hæmoptysis is doubtless compression or obliteration of the pulmonary veins by the tubercular deposit; in consequence of which, blood, interrupted in its natural channels, overflows or exudes into the neighbouring bronchi. If this explanation be correct, hæmoptysis, moderate in amount, must be regarded rather as beneficial than alarming. By preventing the stagnation of unhealthy blood, it must tend to oppose the extension of tubercular disease; and as far as a conclusion may be drawn from the cases under my care, the tendency of hæmoptysis of considerable amount would seem to have been rather favourable than otherwise. You will observe that some of the cases recorded of copious hæmoptysis, were remarkably slow in their progress. In six of the cases the quantity of blood expectorated at once has exceeded a pint, and the time which has elapsed since the occurrence of the profuse hæmoptysis has been in these patients respectively, six months, twenty-two months, twelve months, ten months, eight months, and five years; in several of these instances, evidence of pulmonary disease preceded, by many months, the occurrence of hæmoptysis; and in some the disease has not advanced beyond the first stage. These facts are in harmony with my general experience, as showing that this symptom tends more to retard than accelerate a fatal issue.

The practical bearing of these facts is obvious and important, as impressing the conclusion that undue haste to arrest hæmoptysis should be deprecated, and that as a general rule it is better to moderate this symptom by producing determination to other organs, than to employ direct astringents. You will find great benefit in many cases from the administration of a dose of calomel, or mercurial pill with henbane, followed by the use of half-drachm

doses of sulphate of magnesia with diluted sulphuric acid, administered twice a day.

Let me repeat, that hæmoptysis, when slight, is often useful and should not be hastily checked. When it is considerable, if of an active character, as indicated by a full hard pulse, heat, and oppression under the sternum, and heaving of the diaphragm, cupping, or even bleeding, may be requisite. In less formidable attacks, anti-congestive remedies, and small doses of sulphate of magnesia with sulphuric acid may be given, or antimony with nitrate of potash. Ipecacuanha has been recommended, in doses of two grains every quarter of an hour, but this remedy has disappointed me. If the hæmoptysis be passive, direct astringents may be required, of which alum is one of the best; and perhaps this remedy acts more efficiently when allowed to dissolve in the mouth than when taken in mixture. The following prescription is appropriate for this purpose:—Take of powdered gum-arabic and of white sugar, each three drachms; powdered tragacanth, a drachm and a half; alum, two drachms; catechu, three drachms; rose-water, as much as sufficient for a mass to be formed into sixty lozenges.

The most powerful of direct astringents in the treatment of urgent cases, is acetate of lead. You may give two grains for a dose in a mixture, with half a drachm of distilled vinegar; or if you give it in pill, take care to give acetic acid immediately afterwards, in order to counteract the tendency of the carbonate of lead to produce colic. Gallic acid is not so prompt and effectual as acetate of lead, but suits some cases remarkably well. Turpentine is probably one of the most certain and suitable remedies in a majority of instances. Two drachms of spirits of turpentine, two ounces of mixture of gum-arabic, and four ounces of infusion of matico or of cinnamon-water, with thirty minims of tincture of capsicum, form an appropriate mixture, of which an ounce may be given at intervals. In slight cases, the infusion of matico alone is often sufficient.

When the hæmoptysis is associated with suppressed catamenia and hysterical symptoms, lytta is of great value; but let me repeat the opinion, that in a majority of instances of phthisis moderate expectoration of blood is useful, and that whilst you allay the apprehensions of the patient you may leave the symptom to its own course.—*Lancet.*

### ON THE TREATMENT OF ERYSIPELAS BY SUBCUTANEOUS INFILTRATION OF THE TISSUES.

By DANIEL BRAINARD, M.D.,

Professor of Surgery in Rush Medical College, U.S.

DIFFUSE inflammation, in whatever tissue it occurs, is, in many cases, the results of the introduction of a specific poison into the fluids of the living body. This is sufficiently obvious in instances of dissecting wounds, but more obscure in other cases in which the source of the poison is less palpable. If we consider, however, the manner in which practitioners attending cases of erysipelas, communicate diffuse peritonitis, phlebitis, &c., to puerperal patients; that most cases of erysipelas of the face originate on the surface of the mucous membrane of the throat or nostrils; that, in the members, it commences usually in the lymphatics or glands, and extends to the skin, veins, and areolar tissue; that the situation in which it most frequently occurs is on the scalp, back, surface of a divided bone, and the internal surface of the uterus, where, from the open vessels, absorption most readily takes place; that ulcers from frost bite, bite of animals, and unhealthy ulcers, are those most frequently attended by erysipelas; if, moreover, we compare its effects with that of the poison of serpents, we shall see that there are but few cases of true erysipelas where there is not a wound or ulcer on the surface of which the poison can be found, or where it is introduced from a foreign source.

What is the nature of this poison? We are profoundly ignorant on this point, although from analogy with the poison of serpents, &c., we might infer, with more or less probability of correctness, that it is an acid. In what manner does it operate? Its first effect is upon the lymphatic

glands, its second upon the lymphatic trunks, next on the bloodvessels and areolar tissue near the point of inoculation. The poison acts as a leaven, or by presence and catalysis, not in the first instance on the blood, but on that universally diffused fluid in the system which is extravascular, and in which the action of nutrition takes place. The blood only becomes secondarily changed. How long does it take to act? This depends upon its intensity, its quantity, the degree of predisposition, the point of inoculation, and other circumstances which are unknown. In ordinary cases, perhaps, four days might be considered the average time required from its introduction to the production of severe constitutional symptoms. Is there any method of preventing its action? It seems to me obvious that neither bleeding, purging, vomiting, sweating, nor any known method of internal treatment can effect this cure. Neither can external applications fully do it. Could not the medicine be put in the tissue where the morbid matter is operating? To determine this point, I took a common exploring trocar, and inserting it under the skin of a dog, injected different medicinal solutions. I found they produced suppuration. Using distilled water, the same effect was produced. It was owing, then, to the mechanical breaking of the tissue, not to the medicine. I then tried the common tube used for mercurial injections, which, having a capillary point, might allow it to infiltrate. Here again I was disappointed; it would not infiltrate, or so slowly as to be of no avail. Not discouraged by these difficulties, I determined to make use of it first on the human subject in cases where œdema or erysipelatous effusion had taken place. Two cases treated in this manner were reported to the Chairman of the Committee on Surgery of the American Medical Association, which, as they will be noticed in their Transactions, need not be repeated here.

The manner in which the infiltration is effected is this: A small syringe is furnished with a point drawn down to a capillary tube, into which is fitted a steel point as fine as the finest needle. When this is inserted into the point, they form but one pointed needle, which may be passed like an acupuncture needle in any direction through the tissues, veins, or arterial trunks. The steel needle being withdrawn, and the syringe adapted to the point, the tissue is infiltrated by gradually injecting the desired medicinal fluid, using frictions to disseminate it.

*Case.*—Patrick Marmion, æt. 23, had his hands severely frozen on the 23rd of December, 1851. Some days after, the little finger of the left hand was amputated, an unhealthy wound remaining after it. He applied to me on the 15th of January with the following symptoms:—Left hand and forearm swollen to the utmost limit of the skin; arm much swollen; glands of axilla enlarged and tender; surface of the hand and forearm red; vesications at different points; extreme pain; pitting on pressure; considerable constitutional disturbance. Inserted the point of an infiltrating syringe under the skin on the back of the hand, and slowly passed in a sol. of gr. x. iod. potass. in f. 5iv. dist. water. This was disseminated by frictions. A solution of iodine and hyd. potass. was also applied externally. The first effect of the infiltration was a severe smarting pain, which subsided at the end of a few hours, and along with it much of the pain of the hand. At the end of twelve hours the pain was quite gone; the swelling subsided; on the 20th there only remained a stiffness behind. At this time I amputated the little finger of the right hand. This was followed by enlargement of the lymphatic glands of the axilla; red lines ran along the inside of the arm; redness, swelling, and pain severe, as in the case of the other member. Thinking, perhaps, that the subsidence of the symptoms in the other case, after the use of the infiltration, might be merely accidental, I in this case used the external application of the sol. of iodine and the usual internal means. On the 25th, an abscess had formed upon the front side of the wrist, which I opened. I then attempted to infiltrate the back of the right hand as I had before the other; but spilling by accident half the liquid, only gr. v. iodd. potass. in f. 5ij. of water was thrown in. 27th. An abscess had formed on the under side of the wrist, which

was opened. 29th. Another abscess had formed in the ball of the thumb, which I opened. The case slowly convalesced, *but there was no suppuration in the situation of the infiltration.* It is not indeed certain that it would have occurred there without, but the case proves at least that the infiltration had no tendency to produce it. The solution of the hyd. potash was preferred, because it is well known that it can be thrown into the tissues without producing suppuration, and for theoretical reasons on account of the alkali it contains. Thus far I had only operated on tissues already infiltrated. In case of inoculation by snake bite or other poison, I should recommend, in case the poison had been already absorbed and could not be destroyed by cauterisation, the application of a ligature so as nearly to interrupt the venous circulation. This stops absorption at once, and when at the end of several hours the member becomes œdematous, then the infiltration can be effected. In snake bite the remedy proposed by Dr. Whitmore, a solution of iodine and hyd. potash, should in the present state of our knowledge be preferred. I have ascertained by experiment that œdema of the limbs, sufficient to allow of infiltration, can be produced by ligatures moderately tight so as to give no pain. I think it not improbable that medicines introduced into the system in this manner will, in some cases, act more efficiently than when taken into the stomach or injected into the veins. We know that many poisons act instantaneously when inoculated, and are harmless when swallowed. When introduced into the veins, they are rapidly eliminated by the kidneys. Independently of this, I have reasons for believing that the effects of medicines, when taken into the stomach, when injected into the veins, when thrown into the different serous membranes, and when infiltrated into the areolar tissue, are not identical, but that the method of employing them has a controlling effect on their action.—*Amer. Jour. of Med. Sci.*

#### DECOMPOSITION OF PHOSPHATIC CALCULI BY SOLUTIONS OF LEAD.

By Dr. S. E. HOSKINS, F.R.S.

From cases which have occurred under the author's notice, not only does the bladder, under irritation, tolerate the presence of solutions of lead, but also that they act as sedatives, and exert a favourable influence, directly and indirectly, on the morbid secretion of mucus which generally, in such cases, exists. After having made a trial of most of the vegetable supersalts of lead, all of which act, more or less, as unirritating decomponents, I have returned to the use of that originally proposed, the nitrosaccharate, as by far the most effective. That prepared for me by Mr. Garden of Oxford-street, is much more energetic as a chemical agent than my own, and equally mild in its physiological effects. It is likewise more decidedly an organic salt, which I consider essential to the fulfilment of the ends in view; and I am strengthened in the opinion that sugar is a necessary ingredient, from the perusal of two papers in the July number of the *Pharmaceutical Journal*; one by M. E. Peligot on the "Combinations of Sugar with Lime," and another by M. Barreswill on the "Solution of Carbonate of Lime in the Saccharates."

One grain of the salt, superacidulated with five drops of strong acetic acid, is the proper proportion for admixture with each fluid ounce of water. It is essential that the salt and the acid should be incorporated before the addition of the water, and that the whole should be brought to the boiling point. Superacidulation is necessary on many accounts: it secures perfect solution, increases the decomposing activity of the liquid, and prevents the formation of any carbonate of lead.

As the salts contained in the urine tend to decompose the solution, and lessen its effects on the concretion, the bladder should be evacuated, and washed out with tepid water before the lead fluid is introduced. A double-current caoutchouc catheter is the best for this purpose, as it enables a continuous stream to be employed, and as, on account of its flexibility, it is less liable to irritate the urethra, which should be sedulously avoided. From four

to eight fluid ounces of the solution may be thrown into the bladder at a time, and renewed every ten or fifteen minutes, as often as may be deemed proper. By renewing the liquid at short intervals, much greater effect on the calculus is ensured than when it is allowed to remain longer; for the precipitate formed by decomposition soon envelopes the stone, and puts a stop to further action until a fresh surface is exposed. Exercise during the retention of the injection increases its effect. Some slight revulsion may be produced by the first introduction of this, or any other fluid, into the bladder: when such is the case, the operation should be remitted for a day or two, and cautiously renewed. The injection may be either warm or cold, ■ may be most agreeable to the sensations of the patient. Warmth favours decomposition of the calculus.

If used with proper precautions, I have found that the lead solutions exert as sedative and salutary an influence on the lining membrane of the bladder, as they do on external surfaces under inflammation. They also act upon the mucus, which is so abundantly formed in cases of this nature, coagulating it into short curdy flakes, which are easily passed through the urethra. When the urethra itself is inflamed, or abraded, the injection will be injurious; for the lining membrane of the canal is, I believe, more sensitive than that of the bladder. The introduction, therefore, of decomponents should be had recourse to, either before lithotripsy or after the urethra has recovered from the effects of the instruments employed, but can never be used with any prospect of success where organic disease of the bladder or prostate exists. The injection should not be employed during the internal exhibition of hydrochloric acid, although it may be freely used when nitric acid is administered. When the bladder is not very irritable, a dilute nitric acid injection, alternating with the lead solution, will hasten decomposition.

The two facts established with respect to the lead salts—viz., first their toleration by the bladder, and secondly, their chemical action on calculous concretions, induce me to hope that they may become useful agents in the treatment of various other affections of the urinary organs. I have never presumed to imagine they would prove specific solvents for the stone; but I trust that, where surgical operation is inadmissible, they will be of some avail for relief, if not for cure, by smoothing asperities, and removing the outward phosphatic coating of calculi, so as to bring them within the verge of the crushing forceps; in short, that they may avail for partial, if not for entire, disintegration. The latter is more likely to happen where layers, composed of the urates or oxalates, are bound together by phosphatic cement. On this species of calculus, they are calculated to act as highly carbonated waters do on those of another description. "Nor is the action of highly carbonated waters (says Dr. Prout) confined to their mere solvent effects; they undoubtedly possess disintegrating power; that is, the power of disturbing the attraction, both cohesive and adhesive, by which the molecules of the calculi are held together, so as to render them brittle and easily broken into fragments." This is an additional reason for using decomponents before recourse is had to lithotripsy.

Besides the kind of cases already adduced, there is one variety for which decomponents seem to be peculiarly adapted—viz., concretions in the prostate gland. No instrument hitherto devised has been successful in dislodging them. The first case, however, mentioned in the present paper, goes to prove that a considerable quantity of calcareous matter was removed from the prostatic portion of the urethra by the use of the lead injection. In the first experiment communicated to the Royal Society, it was stated, that one hundred grains of calculus immersed in lead solution for forty minutes had lost twelve grains. In the second experiment, the quantity dissolved, from a fragment weighing thirty-seven grains, was after half an hour's immersion, eight grains. Subsequent experience has verified these observations, and proves that, under favourable circumstances, decomposition takes place in definite proportions; so that from the precipitate of phosphate of

lead, the quantity of ammonio magnesian phosphate which has been decomposed may be securely estimated.

Since these circumstances obtain out of the bladder, by means of a fluid which can be borne by that organ with impunity, we may reasonably hope that the mere transference of the scene of action from the exterior to the interior, will not materially affect the results.—*Lond. Jr. of Med.*

## REMOVAL OF OSSEOUS AND CARTILAGINOUS BODIES FROM THE KNEE-JOINT.

By JOHN FREDERICK MAY, M.D.,

Professor of Surgery in the National Medical College, and one of the Surgeons to the Washington Infirmary.

— *Tabler*, aged 51, entered the Washington Infirmary in October, 1845. The left knee-joint is very much enlarged, the capsule being greatly distended by the synovial fluid, and two very large moveable bodies can easily be detected floating in it. These bodies, on examination, appear to be very hard, and they can be made to pass and repass from one side of the joint to the other by slight pressure. The motions of the articulation are almost entirely suspended. He can flex it very slightly, but the effort to do this is attended with considerable pain.

The patient says that he accidentally opened the joint thirty-five years since with a hatchet, near the upper and outer side of the patella, and that a portion of the synovial fluid escaped through the wound. He also injured the joint at twenty years of age, in jumping over a snow bank, and was unable the next day to move it without occasioning great pain from one of the foreign bodies getting under the knee-pan. It was at this period that he discovered for the first time that there was something loose in the joint. There seemed then to be but one, and that about the size of a grain of corn. Ever since the joint has been subject at different periods to become very much distended and painful from accumulation of the synovia. This was generally the result of some injury or fatigue of the joint, for when kept quiet the swelling and pain would disappear. Since February last he thinks the bodies have increased considerably in size.

He was made aware of the risk in opening the articulation to the extent that would be necessary to extract substances so large as these evidently were, but he manifested a perfect willingness to submit to any operation.

Previous to their removal he was kept on low diet and in bed for a week, with the limb perfectly still. Leeches and cold fomentations were applied to the joint, and his bowels were well evacuated. Having taken these precautions, they were removed in the following way:—Both were first brought to the inner side of the articulation, and held there by the fingers of the left hand being placed above them; the integuments were then drawn forcibly upwards by an assistant, and an incision one inch and a half long was made down to the capsule, the opening into which was made rather less than the external one. The largest substance was instantly slipped through it, and was followed by the smaller one, not more than a teaspoonful of the synovial fluid escaping with them. The upward traction of the integuments being removed as soon as the bodies passed out, the correspondence or parallelism between its wound and that of the capsule was, of course, destroyed, and the further escape of the fluid and the entrance of the air was thus guarded against. The wound was closely covered with adhesive plaster, and a compress soaked in cold water was placed around the joint. The limb was put in splints, the cold applications continued, and low diet still enjoined. Not the slightest pain or unpleasant symptoms followed the operation, and the wound united throughout by the first intention. The patient was allowed to use the limb gently at the end of a couple of weeks. He soon after recovered the entire use of the joint. The measurement and weight of the two bodies were as follow:—The largest: length two inches, breadth one inch and one-eighth, thickness nearly three-fourths of an inch, weight 301 grains. The smallest: length one inch and a half, breadth seven-eighths of an inch, weight 175 grains. They were very hard, being of osseous consistence; in shape oval, convex on one side and flat on the other; the surfaces of each presented a rough and irregular appearance, traversed by a number of smooth sulci or depressions. They are still in my cabinet, and are the largest bodies that I have ever seen extracted from an articulating cavity. On sawing through them longitudinally, the interior was found to be as white and almost as hard as ivory. In the largest there was a number of cells lined by a delicate epithelium; the cellular structure of the

finisimal doses; if derived from large doses, they are for the most part *secondary* effects, and therefore not homœopathic; on the other hand, it were the grossest error to attribute to infinitesimal doses all the effects of ordinary ones. To deny that the *sensible* effects of matter are not diminished with the diminished quantities of matter, is to deny an universal law of Nature to which no exception is known.

7. The theory of 'potencies' which Hahnemann has invented to get over this difficulty is a return to the occult science of the dark ages—a pure unadulterated mystification.

8. The presumed action of infinitesimal remedies on the sick body is open to the same objection as the presumed action of infinitesimal substances on the healthy body. Both are imaginary.

9. Any person of common observation can convince himself by experiment that medicinal substances in infinitesimal doses do not produce the effects attributed to them by the homœopaths.

10. Hahnemann's rejection of local or external diseases is not founded on facts; and his theory of so-called local diseases, all of which (except the syphilitic) including even disorders of the mind, he refers to hereditary itch, is a monstrous absurdity.

11. The alleged results of homœopathic treatment, paraded with the appearance of accurate statistics, have abundant internal evidence to prove that they cannot be relied on in the very slightest degree; and even on their own showing, and giving the homœopaths all the advantage of selected cases, they show an enormous amount of mortality."

It has always appeared to us to be as much a part of the duty of the educated medical man to seek to remove error as to advance science; and to endeavour, as far as in him lies, to open the eyes of the public to the impositions practised upon them by homœopaths and other charlatans, as it is to use his best exertions to improve the healing art, and to advance the knowledge of disease: and if he has the honour and dignity of the medical profession at heart, he will make as broad as possible the line of demarcation between the honest practitioners of the healing art and those spurious offshoots of it, who, whether entitled or not to write M.D. after their names, belong not to us, and are repudiated by us. This has been Dr. Bushnan's aim in the work under notice, and we wish it every success.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JUNE 9, 1852.

### ORGANIZATION OF LOCAL MEDICAL ASSOCIATIONS.

In our last number we printed a circular calling on the members of our profession to organize Local Associations with a view to full coöperation, and signified an intention to allude to the subject without delay; a promise which we have now to keep by a brief glance at the objects which such a measure may effect. It may, we believe, do much good by creating an executive to carry into operation such plans as the members of our body may consider necessary for their safety, making known to the constituted authorities their wants, and suggesting the methods by which defects might be remedied. Such associations may also be of use by pointing out the imperfections of laws affecting the medical profession generally, and the evils resulting from their imperfect execution or their perversion. By them also the oppressive acts of the local authorities can be resisted when individuals are disabled from defending themselves by peculiarity of circumstances; even to the extent of putting the law in motion for the protection of those who require it. These objects and much more may be accomplished by this means; but our belief is that the more limited the sphere of operation the more valuable will be the results. All speculative, controversial, or irrelevant questions must, we think, be resolutely eschewed,

and nothing entertained but that which has a direct bearing upon the present condition of men in practice. Even matters of importance will sometimes prove difficult of management when the handling of them involves conflicting interests. With such questions as Medical Reform, Educational Legislation, or redress of remote grievances, the less meddling the better; for they are cared for already: and with Loyal Addresses to official functionaries the less the better too; in fact *business*, and nothing else, should engage the attention of men who have little time to spare, and to transact that every arrangement should be made calculated to do so by the shortest and simplest means. If at any time a public expression of feeling or opinion becomes necessary, it should be elicited by the invitation of the bodies proposed to be formed, and not made directly by them: nothing so much interrupts the calm progress of business as the speaking and writing which successful agitation demands. These restrictions, we venture to suggest, although we are convinced they will appear to many superfluous and of too stringent a nature, but having had some experience in such matters we consider the warning they convey may prove valuable. It may, however, be objected to this proposal that it is unnecessary, and may prove mischievous by promoting discord in our body and hostility to constituted authority. The necessity, however, we are bound to admit when those who are most interested assert it, and the fear of discordant results and hostile demonstration seems not to be entertained by the originators of the plan. It is true that many prudent or cautious men are of opinion that the functions proposed to be discharged by these Local Associations may be more effectually discharged by existing bodies of more permanent character; but we feel inclined to agree with those who think that there are proceedings necessary for the safety of individuals which can be conducted by voluntary associations only, while there are others which none but chartered or official authorities can effectually advance. The College of Surgeons, for example, has done, and we hope will continue to do, a great deal for the promotion of professional objects, but from the nature of its construction it must necessarily refrain from acting on occasions when action is required: when its members are not agreed as to any particular line of policy affecting them personally, or when the performance of duties incompatible with the charter is demanded, how can a corporation proceed with safety? With respect to the apprehension that hostility to constituted authority, or a spirit of resistance to the execution of the law as it stands may be engendered by the proposed organization, we cannot believe that it is well founded. There is no reason in the world why men should not contribute to the harmonious working of a plan by a calm and candid contemplation of difficulties, rather than cause its defeat by rash assumptions. At the moment we write hundreds of our brethren are smarting under the effects of the sweeping changes which have just taken place, but it is a great mistake to suppose that the remedy for this lies in a hostile opposition; on the contrary, as it appears to us, the present policy should be to rely upon the law such as it is, and to trust to its faithful and impartial execution for a mitigation of its severity; for we are convinced that by a firm determination to enforce its provisions more can be done than by any effort to nullify them. Some may perhaps wonder that we should thus suggest a pacific policy, but there is a time for all things, and whenever the period arrives for a different course, we shall, we hope, be prepared to pursue it.

## MEDICAL REPRESENTATION IN PARLIAMENT

To prove to our readers that our conceptions respecting the possibility of securing a representative or representatives of the Medical Profession in Parliament were neither premature nor visionary, we copy for them a report of a speech of Lord DERBY, since delivered, which touches the subject. It is true that his Lordship does not speak in very encouraging terms of such representation, but he concedes the principle upon which a claim to it must rest, and that is enough for the present. We have the numbers; and whatever coxcombs of other pursuits may say to the contrary, we have the intelligence required. All we want is the spirit to enforce our claims, the self-respect which, strange to say, is deficient, but which, if cultivated, will open our eyes to the true nature of our position in the body politic. Knowledge, they say, is power, and the period has arrived for settling what that knowledge is which confers this power:

The Earl of Derby said that there could be no doubt that in consequence of the changes effected by the Reform Bill, and the abolition of rotten boroughs, there had arisen increased difficulties in the way of men of science and learning in various professions, who were not well known to the general public, and not possessed of that fluent oratory requisite for conciliating popular suffrages, making their way into parliament. Under the former system there was one way in which science and the colonial interests were indirectly represented in the House of Commons; and there were means by which young men disposed to avail themselves of seats in parliament, not for amusement, but for the service of their country, might make for themselves as laymen characters in that service. To a great extent those facilities were removed under the existing system. Moderate men—men of good sense and judgment—who were not of extreme opinions, might in these days find it much more difficult than it should be to get into parliament. He thought, also, it was not just or right, but was most inexpedient and impolitic, that everything should be referred in this country in the shape of representation to a mere question of numbers. If, however, it was necessary to enter upon an entirely new distribution of the constituencies, or merely to supply vacancies, or to make alterations which time and circumstances might require in the state of the representation, it would be exceedingly unwise to look to the single question of numbers without taking into consideration the question of property, and, as far as it could be made matter of legislation, the question of intelligence (hear). No doubt the numerical element commended itself most to the popular voice, and was most easily ascertained. The next in the scale of facility of ascertainment was that of property, but it would be most difficult to legislate in such a manner as to give a due fairness in constituencies to intelligence. If what his noble friend suggested produced a certain number of constituencies, they might assume that, exclusive of numbers or property, they would represent the intelligence of the nation. At the same time, although it was very difficult to introduce that element to any great extent, he was far from thinking it would be undesirable to introduce into our representation the question of intelligence and education as apart from that of mere numbers or property. To a certain extent it was adopted in our representative system by the introduction of members for the Universities of Oxford and Cambridge, and also of Dublin; and if there were other bodies sufficiently numerous—because he could not altogether overlook that point in dealing with a popular representation—and also sufficiently distinguished in point of science to be placed on the same footing with those universities, he thought such bodies would have a fair claim to be considered. That subject had not escaped the attention of the government, and even upon a recent occasion they had anxiously sought for the means of making some addition to the constituencies in that point of view. Take the Scotch universities. No doubt they were as desirous as the English of being represented in parliament; but there were three or four separate universities in Scotland, some of them exceedingly the reverse of numerous, and altogether not giving a very numerous constituency from those who graduated there; and he was not sure they would all receive such a proposition as a boon, as the smaller universities might think that in their representation the general interests of science might be over-

borne by the larger bodies. Then, again, there were the inns of court. They were bodies, no doubt, capable of furnishing most respectable and valuable constituencies, and probably would return to parliament very useful members; and he did not mean to say it would not be highly creditable to any lawyer to be returned, rather than by a general constituency, by those who belonged to the same profession as himself, to sit as the parliamentary representative of the lawyers of England. But of all classes of the community, the class that appeared to find the least difficulty in coming into parliament were lawyers (hear, and a laugh). The tendency of the existing system was that which in America and other countries was considered objectionable—the great influx of professional men into the House of Commons; because they were precisely the men who, from going circuit, had the means of making themselves known and gaining local influence. When, however, his noble friend went to learned societies, he would find greater difficulty than with regard to universities or courts of law, and he was not quite sure the introduction of the political element might tend in all cases to the harmony of different bodies. Take the College of Physicians and the College of Surgeons. If they combined the two he was not sure the element of discord would not be introduced among them (hear); and, as to each particular body, he did not know that it would be for the benefit of either, as such, that they should have the power of returning a representative to parliament. Nor could they combine a vast number of these societies and desire them all to return a representative: it would be impracticable. Still less possible would it be to give to each of those bodies their share of representation in parliament. Again, many of those societies, though learned, technically so-called, introduced members who had no claim to represent science, and who were admitted only for their rank and station as honorary members; but if they gave them the extra inducement of a share in the representation, they would run the great risk of endangering the primary object of them—namely, the advancement of science, and of converting them into political engines.

## CORRESPONDENCE.

## MEDICAL LIFE IN LONDON.

London, June 4, 1852.

A glance at the London hospitals and London men may interest the many readers of the MEDICAL PRESS; it will at least furnish an insight into the materials of which the vast medical community here is composed. Medicine in England, as compared to Ireland, as a general rule, is a most unhappy trade: money and a brougham the grand climax of every thing. The little peddling chemist prescribes over the counter—every thing is “doctor’s stuff,” and the little chemist if he only manages to sell tooth-brushes, soap, and “doctor’s stuff” enough, is soon recognized by the heads of the profession. One dash more, and he gets into parliament. In the meantime, the honest, well-educated physician or surgeon struggles on, a world of jealousies in the so-called weekly journals besetting him. In the London hospitals, and the more select practice of the west-end, one sees the practice of physic as it is in Ireland: not a trade, but a profession. We may do some good, then, by a few comparisons of medicine as it ought, and as it ought not, to be. We take the hospitals at random.

The *brusquerie* of Ramsbottom to the poor, and the lectures on “Fractures” of Luke at the London Hospital, are things to be amused with, not described; Cobb’s practical clinique, however, somehow makes amends, and the wholesome want of faith in all English physic of Pereira. You have some good men, of course, among these “wise men of the East;” among the foremost of whom I would place Dr. Carpenter, though not a happy lecturer, and Mr. Critchett, a young and active ophthalmic surgeon, also Mr. Ward. There is a fair share of humbug and nonsense in all the London hospitals; but our Mile-end allies, perhaps, bear off the palm. An excellent spirit exists between the students and teachers; white-bait dinners at Greenwich of every one in the hospital—surgeon and student—are quite the rage during the summer session. The London Hospital contains something like 400 beds; about two-thirds of which are allotted to surgical cases, the majority the graver sorts of accidents, explained by the vicinity of the London and East India Docks, and the tremendous Milesian rows among the Irish of Whitechapel. It is an hospital little visited by strangers to London, and as a general rule, has very little in the shape of novelty to recommend it.

The aristocratic school in London of course is Guy’s; and

we must do the pupils there only justice, from a long acquaintance with them, to say, that we have never met men so intent on study, or who so well combine correct and gentlemanlike deportment with hard work. The favourite (as he deserves to be) at this school is Bransby Cooper. With a peculiar twinkle of his very peculiar eye, and an inward little chuckle at saying something very good, Bransby Cooper lays down the simplest things in surgery in a way that attracts all the classes to his lectures. One regrets sometimes he says he does such and such a thing because "his uncle used to do so." Bransby has only to will it to be a very great man himself, not a copy, which is ever to be deprecated. His clinical lectures have much of the unctuous fun of Mr. Cusack or Bob Adams, once on a time, at the Richmond; his practice at the west-end is more like that of Sir Philip Crampton's; his manners are peculiarly kind and gentlemanlike; his observations going round the hospital show him to be a highly practical and very well read man; in advance, indeed, in histology and other matters, of his more ordinary contemporaries. Edward Cock, however, is the working man at Guy's, and if he did not take as much snuff as—whom shall I say?—William Stokes, he would be perhaps less of a character. He does not say much among the pupils; he is eminently near-sighted, and except one is right up to his spectacles you cannot converse with him. Cock, notwithstanding his *presbyopia*, is an admirable operator; he is in capacity of house-surgeon more than anything else, and does all the rough work. His opinion on any surgical matter is, perhaps, the most valuable and practical in London; indeed, with the more theoretic and often valuable opinions of Birkett and Golding Bird, Guy's may boast of the most advanced views on surgery in the three kingdoms. Syme, and his fellow micrologists, may perhaps be more original in Edinburgh, but the vast field of practice at Guy's must counterbalance everything else.

Of the third great surgeon at Guy's, Mr. Hilton, one of the most rising men in London, we need only say he is quite equal to the other two. He is a first-rate anatomist; and if it be any test of his popularity, the crowd of students who follow him is twice that of the other men. He is perhaps the best operator in England. Guy's has nearly 600 beds, besides an out-door attendance on many thousands every month. A very valuable subterranean dispensary, exclusively for children, is taken care of by Dr. Golding Bird, but we cannot say we have ever seen many novelties in this department. Dr. Lever's name is perhaps more generally known in connexion with diseases of females. Of the other physicians—first-rate in their way—Dr. Addison, Dr. Babington, and Dr. Barlow, we may take some other opportunity of speaking. Addison is, perhaps, the true ideal of the practising physician—the Corrigan or Marsh of this side of the channel; Babington is better read—the Graves of London; while Dr. Barlow, pursuing "the even tenor of his way," a very first-rate practical man, is like nobody else perhaps but Dr. Barlow. All work very harmoniously together; and if there is anything at Guy's superior to its surgery, I would say it is the practice of physic of Addison. Dr. Gull is a physician now spoken very highly of; indeed he and Birkett are among the best of the men at Guy's.

The practice of physic at either of these hospitals, or by any of the men at either the London Hospital or Guy's, is as much like the petty trading of the general practitioner and chemist, as the elegancies of the barber's pole and basin are like to the writings of John Bell or Hunter. Writers are ever confusing the two. As a profession, there is nothing more grand and beautiful than medicine: as a trade, nothing more horrifying. Forty thousand copies of a medical journal, it is said, are just sold this week to further this trading propensity. A dinner also held for the Medical Benevolent Fund, in which the horrors of the starving members of the profession are sufficient to freeze the blood, and this in England is called advance! Many hundred surgeons, members of the Colleges and Hall, emigrate and fix themselves in other occupations. The Lincoln's Inn folk punish quackery if a hundred miles off, and the Hall does the same; a sweltering mass of quackery all round them in London, due to their negligence and apathy, and the want of proper moral control all such bodies should possess.

(To be continued.)

#### TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—My attention was only yesterday directed, by a letter from my friend Dr. Whittaker of Ballina, to Dr. Lynn's case of retention of urine, reported in the PRESS of 19th inst.

As the very great majority of these cases, whether in or out

of the County Infirmary, pass through my hands, the question might suggest itself to others (as it did to my correspondent) "had I seen it, and coöperated in the treatment pursued?" I therefore beg leave to acquaint my friends among your readers, that the first I heard of the case was on the occasion of reading the report in the PRESS.

Published cases being of course open to criticism, I would wish, in all courtesy, to offer a very few observations on this one, and to enter my decided protest, *quantum valeat*, against the practice pursued.

The case was manifestly one of that very common form of senile retention from enlarged prostate; when the instrument passed the opening into the false passage (*situated very near the orifice*) "it passed on to the bladder with the greatest facility," and subsequently the operator "had not the slight difficulty in introducing the instrument twice and thrice daily." In fact, the excuse of impermeable or complicated stricture is never once pleaded for the subsequent very heroic operative practice adopted; and, in my mind, such alone could excuse such a procedure as forced catheterism, while very many most eminent surgical authorities maintain (and with undoubted propriety) that of all the means for the relief of retention it is the most hazardous. But in a case of retention from enlarged prostate, where, as described, the instrument had been many times introduced "with the greatest facility," and "without the least difficulty," I confidently submit it to the "conscript fathers" of Irish surgery, whether the *tunnelling* a route to the bladder through a false passage, commencing so near the orifice of the urethra, was not a measure not only unnecessary but to the last degree dangerous. That this *tunnelling* was the cause of the subsequently nearly fatal urethral or vesical hæmorrhage, is so evident as to require no argument; and that the patient survived is, I confess, very remarkable indeed. But I should be sorry to impress a young practitioner with the idea that he could with impunity follow a similar practice with every (or any) urethra, and expect a similar result.

If patient and skilful manipulation had really failed to pass the point of any sized catheter over the orifice of the false passage, I should, in such a case, with the sanction of my brethren in consultation, have practised the very proper deception of tapping the bladder from the rectum without consulting my patient's wishes, or at all informing him of what I was about to do. Life is not to be sacrificed, or a surgeon to be intimidated from pursuing the dictates of his judgment by the ignorant whim of a patient.—I am, dear sir, faithfully yours,

Wm. S. LITTLE, A.B., M.D.,  
Surgeon of Sligo County Infirmary.

Sligo, May 29, 1852.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

At the Annual Meeting held on Monday, the 7th inst., the following Officers were elected to serve for the ensuing year:—

President—EDWARD HUTTON.

Vice-President—WILLIAM HARGRAVE.

Secretary—ALEXANDER READ.

COUNCIL.—Sir Philip Crampton, Alexander Read, Arthur Jacob, William Tagert, Thomas E. Beatty, Andrew Ellis, Robert C. Williams, Robert Adams, James Barker, William Colles, John H. Power, Lewis E. Lipsett, John Macdonnell, Michael H. Stapleton, Philip Bevan, Hans Irvine, James S. Hughes, Robert Pentland, Samuel G. Wilmot.

#### MEDICAL BENEVOLENT FUND SOCIETY.

DR. J. F. DUNCAN, Treasurer *pro tem.*, acknowledges with thanks the receipt of the following sums since last report:—

Dr. Frith, Limerick	£1 0 0
Dr. O'Brien, Ennis	1 0 0
Dr. Donaldson, Crossmaglen	10 0
Dr. Thornhill, Fitzgibbon-street	1 0 0
Dr. A. Duncan, Finglas	1 0 0
Half-year's dividend on Dr. Hood's donation of four City of Dublin Steam Company's Shares (per Dr. Geoghegan, York street)	
Dr. Purdon, Killeshandra (per Dr. Roe)	1 0 0
Dr. Kenny, do. (per do.)	10 0
Dr. Horan, Cootehill (per do.)	1 0 0
Dr. Aikin, Merrion-square (per Mr. Black)	1 0 0
Dr. Jacob, Ely-place (per do.)	1 1 0
Dr. Mayne, Gloucester-street (per do.)	1 1 0

OBITUARY.—At Wazzeerabad, on the 5th of April, of the fever of the country, Assistant-Surgeon John J. E. Jacob, 10th Foot, eldest son of Dr. Jacob of Maryborough.

**COUNTY OF LIMERICK MEDICAL ASSOCIATION.**

At a Meeting of the above Association, held at the Court-house, Rathkeale, on Friday, the 4th of June,

JOHN PEIRCE, Esq., M.D., Chairman,

it was resolved—

That the Secretary having laid before us the communication from the "Chairman, Treasurer, and Hon. Secretary to the Association of Medical Officers of Dispensaries and Fever Hospitals of Ireland of the 18th of May, relative to the organization of County Associations," we are prepared to coöperate with our brethren throughout the kingdom in effecting the objects stated in that communication.

That the thanks of this Association be given to Doctors Kingsley, Morrison, and Waters for their untiring and valuable exertions to promote the welfare of our profession, and particularly for their present effort to organize County Associations, which we deem to be the most effectual means of "protecting ourselves" and raising the profession "to that high position in society to which it is so eminently entitled."

JOHN PEIRCE, M.D., Chairman.

CHARLES PATTERSON, M.D., Secretary.

**THE MIDLAND RETREAT,**

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coweter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

ON SOME OF THE PRINCIPAL EFFECTS RESULTING FROM THE DETACHMENT OF FIBRINOUS DEPOSITS FROM THE INTERIOR OF THE HEART, AND THEIR MIXTURE WITH THE CIRCULATING BLOOD.

By Wm. S. Kirkes, M.D.

As an introduction to the subject, the author observed that it was a clearly established fact that the fibrinous principle of the blood might, under certain circumstances, separate from the circulating fluid, and be deposited within the vascular system, especially on the valves of the heart. The forms of fibrinous concretions to which the following observations especially applied, were—1st, the masses usually described as Laennec's globular excrescences; and 2ndly, the granular or warty growths adhering to the valves, and presenting innumerable varieties, from mere granules to large irregular fungous or cauliflower excrescences, projecting into the cavities of the heart. These growths, when once formed, whatever might be their origin, were full of peril, and would often remain so, long after the circumstances which gave rise to them had passed away. When of large size, or loosely adherent, they might at any time be detached from the valves, and conveyed with the circulating blood, until arrested within some arterial canal, which might thus become completely plugged up, and the supply of blood to an important part be suddenly cut off, from which serious, if not fatal results would ensue; or smaller masses might be detached, and pass on into arteries of much less size, or even into the capillaries, whence congestion, followed by stagnation and coagulation of the blood, and all the consequent changes such coagulated blood is liable to undergo in the living body, would necessarily follow. Many singular morbid appearances observed in internal organs, and not well accounted for, were probably brought about in this manner. Again, the masses of fibrine might soften, break up, and discharge the finely granular material resulting from their disintegration into the circulating blood, and contaminating this fluid, might excite symptoms very similar to those observed in phlebitis, typhus, and other analogous blood diseases.

Thus the fibrinous material detached from the valves, or any other part of the interior of the heart, might be the cause of serious secondary mischief. The parts of the vascular system in which these transmitted masses of fibrine might be found, would in great measure depend upon whether they were detached from the right or left cavities of the heart. Thus, if from the left, they would pass into the aorta and its subdivisions, and would be arrested in any of the systemic arteries or their ramifications, and especially into those organs which receive large quantities of blood direct from the left side of the heart, as the brain, spleen, and kidneys; on the contrary, if escaping from the right cavities, the lungs would necessarily become the primary, if not the exclusive, seat of their ultimate deposition. A division of the subject being thus naturally formed, the author proposed to consider the subject, first, as to the remote effects resulting from the separation of fibrinous deposits from the valves or cavities of the left side; and secondly, as to the corresponding effects produced by the detachment of like deposits from the valves or cavities of the right side of the heart. The author then proceeded to elucidate the first branch of the subject, in which masses of some magnitude were detached from the left side, and arrested in an arterial channel of notable size. This pathological fact was illustrated by three cases, in many respects identical; for in each death appeared to ensue from softening of the brain consequent on obstruction in one of the principal cerebral arteries by a mass of fibrinous material, apparently detached from growths on the left valves. The first case was that of a female, aged 34, of pale and delicate aspect. She had suffered from rheumatic pains, and there was a loud systolic murmur heard over the entire cardiac region. While under treatment for these symptoms she suddenly fell back as if fainting. She was found speechless, with partial hemiplegia of the left side, but there was no loss of consciousness; the hemiplegia increased, involved the face and limbs, and gradually became complete in regard to motion; but sensation remained unimpaired. These symptoms lasted five days, when she quietly died. The post-mortem examination developed

much congestion of the pia mater, amounting, in some places, to ecchymosis. The right corpus striatum was softened to an extreme degree—being reduced to a dirty, grayish-white pulp. In the posterior lobe of the right cerebral hemisphere was a similar spot of pale softening. The right middle cerebral artery, just at its commencement, was plugged up by a small nodule of firm, whitish, fibrinous-looking substance, not adherent to the wall, but rendering the canal almost impervious. The vessels of the brain were generally healthy, except a yellow spot or two in the coats of those at the base of the brain. The heart was enlarged; several broad white patches externally. The right valves were healthy, so also were the aorta; but the mitral valve was much diseased, the auricular surface being beset with large warty excrescences of adherent blood-stained fibrine. The right common iliac artery, about an inch above the origin of its internal branch, was blocked up by a firm, pale, laminated coagulum, which extended into the internal iliac. The pleurae were adherent in places; liver and intestinal canal healthy; spleen large, pale, and soft, and contained a yellowish-white, cheesy substance. The kidneys were pale, rough, and granular; within the cortex of the right were several large masses of yellow deposit, surrounded by patches of redness. Death had resulted in this case from the softening of a large portion of the right side of the brain, which the author considered to have arisen from an imperfect supply of blood, consequent on the middle cerebral artery of the same side being obstructed by a plug of fibrine. The author then discussed the sufficiency of such an obstruction to produce the effects ascribed to it, and he brought forward many examples showing that atrophy and disorganization usually resulted from any circumstance which materially impeded, or entirely cut off, the supply of blood to a part. The author then directed attention to the probable source of the fibrinous plug found in the middle cerebral artery. The suddenness of the cerebral symptoms rendered it probable that the blocking up of the artery was equally sudden, and not the result of gradual coagulation of the blood within the vessel. The absence of all local mischief in the coats of the artery at the point of obstruction, as well as elsewhere, pointed to some other than local origin for the clot; and the author, at the time of the examination, formed the opinion, that a part of the fibrinous deposit on the mitral valve had become detached, and carried by the stream of blood, until arrested at the angle whence the middle cerebral proceeded. This explanation suited equally for the plug found in the common iliac; for it was quite conceivable that portions of the loosely adherent fibrine might be easily detached by the stream of blood washing over the mitral valve, and when once admitted into the circulating current, they would only be arrested by arriving at a vessel too small to allow their-transit along its canal. Two other cases were described by the author, possessing many interesting points of resemblance; one, a female, aged 24; the other, a male of the same age. Both were admitted into the hospital with hemiplegia of the left side: each had heart-disease, indicated by a loud systolic murmur. The post-mortem examinations revealed the following morbid appearances common to both:—Softening of a limited portion of the brain, producing death by hemiplegia: obliteration of the cerebral artery supplying the softened part; coagula in one of the iliac arteries; fibrinous deposits in the kidneys and spleen; and the presence of fibrinous warty excrescences on the valves of the left side of the heart. So many and such rare features of resemblance could not fail to demonstrate a very close connexion between the several morbid appearances so exactly reproduced in each case. The author believed that these three cases satisfactorily established the two following conclusions—1st, that softening of a portion of the brain, with attendant loss of function, might result from obstruction of a main cerebral artery by the lodgment of a plug of fibrine within its canal; 2ndly, that the foreign substance thus obstructing the vessel was probably not formed there, but was derived directly from warty growths situated on the

left valves of the heart. The author thought it not improbable, although in the absence of direct proof it was but supposition, till further investigation confirmed these facts, that many cases of partial and temporary paralysis suddenly ensuing in one or more limbs of young persons, especially if accompanied with signs of cardiac disease, might be due to interruption of a proper supply of nutriment to the brain by the temporary plugging up of a principal cerebral artery by fibrine, detached from a diseased valve on the left side of the heart. Other arterial branches, besides those of the base of the brain, might arrest these fibrinous deposits derived from the valves of the heart. In Cases 1 and 2, coagula were found in the iliac and femoral arteries; and in Case 3, in the renal. The author thought that many specimens found in museums, and supposed to illustrate the spontaneous coagulation of the blood, or the deposition of fibrine within a limited portion of an arterial trunk, were probably to be referred to the same cardiac origin, and he illustrated the point by reference to a preparation in the museum of St. Bartholomew's Hospital. The second subject of inquiry consisted of an examination into the effects produced by smaller portions of fibrine detached in a similar manner, but arrested in the minute arterial branches, or even in the capillaries. The author thought that the singular masses of yellow fibrinous substance found in the spleen and kidneys, and other organs, and hitherto described as "capillary phlebitis," "metastasis," or "fibrinous deposits," were derived from this cause. Out of twenty-one cases in which the author had observed these deposits in the spleen and kidneys, or other parts deriving blood directly from the left side of the heart, in nineteen there was disease of the valves, or of the interior of the left side of the heart. In fourteen of these there were fibrinous growths on the surface of the left valves; in the remaining five there was simple mention of valvular disease. The author thought that the mere fact of so large a number of cases of so-called "capillary phlebitis" being associated with the presence of fibrinous deposit on the valves of the heart, suggested a very close relation between the two morbid states. The author then entered upon the third branch of this part of the subject, concerning the series of effects which might result from the introduction of fibrinous particles into the circulating blood, manifesting phenomena indicative of the existence of a morbid poison in that fluid. A case was related of a youth, aged 14, admitted into the hospital with obscure typhoid symptoms, the surface of the body being covered with petechiæ. Delirium, with much febrile prostration, followed; he became subsequently comatose, and died. Upon examination of the body, the surface was found covered with petechiæ. The pia mater was infiltrated with what seemed recently effused blood. The surface of the brain thus presented a blotchy appearance, and amid these spots were yellow-coloured patches of various size; some were of a greenish-yellow hue, and had the appearance of being smeared over with pus. The brain was unduly congested, and some ecchymosis near the surface; the cerebral arteries and sinuses healthy; several petechial spots on the surface of the heart, as well as in the cavities; and on the auricular surface of the mitral valve some white fibrinous vegetations, very soft and friable; a like deposit on the aortic valves, with evidence of ulceration; several yellow masses of fibrinous deposit on surface of spleen; cortical part of the kidney covered with minute petechial spots, in the centre of which was a buff-coloured dot; several large yellowish blotches extended deep into the substance of the cortex. The intestinal mucous surface was covered with petechial spots, which were apparent also on the mucous membrane of the bladder, pharynx, œsophagus, stomach, larynx, and trachea. The author considered the mystery of this case cleared up by the post-mortem examination. The attack had been ushered in by a severe pain in the right groin, which was rheumatic; then ensued rheumatic inflammation of the mitral and aortic valves, with ulceration of the latter, and deposition of fibrine. From these deposits portions had probably separated during life, and were transmitted with the blood to all parts of the body,

and being arrested in the capillary networks and smaller arteries, produced the various petechial and buff-coloured spots above described.

The second part of the paper related to the effects which might result from the detachment of fibrinous deposits from the right valves of the heart. Reference was made by the author to a paper on the Formation of Coagula in the Pulmonary Artery, by Mr. Paget, published in the Transactions of the Society, as well as to a specimen in the museum of St. Bartholomew's Hospital, in which there was deposition of fibrine on each of the pulmonary valves, with old coagula filling many of the branches of the pulmonary artery. In this case several large, solid, fibrinous masses were found in the substance of the lungs, presenting appearances not unlike portions of old pulmonary apoplexy. Lastly, the author recapitulated the principal points which he was desirous of establishing, viz.,—1st. That fibrinous concretions in the valves of the heart admit of being readily detached during life. 2ndly. That if detached and transmitted in large masses, they may suddenly block up a large artery, and thus cut off the supply of blood to an important part; if in smaller masses, they might be arrested by vessels of smaller size, and give rise to various morbid appearances in internal organs; or the particles mingled with the blood might be but the *débris* of softened fibrine, yet with power to produce a poisoned state of the blood, and bring on typhoid or phlebitic symptoms. 3rdly. That the effects produced and the organs affected would be in great measure determined by the side of the heart from which the fibrinous material had been detached: if from the right side, the lungs would bear the brunt of the secondary mischief; but if, as was most commonly the case, the left valves were the source, the mischief would be more widely spread, and might fall on any part, but especially on those organs which were largely and directly supplied with blood from the left side of the heart, as the brain, spleen, or kidneys.

In the discussion which ensued on Dr. Kirkes' paper, and which was prolonged far beyond the usual hour of adjournment, several gentlemen addressed the Society. All the speakers, however, eulogized the paper as a very able and masterly production; but several of them took exception to the conclusions arrived at by the author respecting the last two series of cases. It was admitted by all that the researches of Dr. Kirkes opened a wide field of observation; and with reference to the first class of cases, that they threw light on the cause of many obscure instances of softening of the brain, respecting which we had hitherto been unable to form anything better than a conjecture.

#### MEDICAL SOCIETY OF LONDON.

MR. B. W. RICHARDSON exhibited to the Society a new form of stethoscope which he had recently invented. With reference to conveyance of sound, this stethoscope did not differ from other kinds, but it was much more portable and convenient. The improvement lay in the ear-piece, which was joined to the tube by means of a very simple hinge-joint, on the principle of the joint used in the enema syringe, so that the ear-piece could be folded down upon the tube when not in use (like the top of a round table), and could then be carried in the breast pocket without causing the slightest inconvenience. The joint was also so managed that the instrument could be used with the ear-piece standing at different angles, an advantage of some importance. Two other stethoscopes were likewise shown in which the ear-piece moved down upon the tube, but these, though simple in construction, were not so complete as the one above described. The stethoscope was made by Weiss and son, and was of moderate cost.

#### CASE OF GANGRENE OF THE LUNG.

Dr. HALLEY read an extract from a letter giving an account of an interesting case of gangrene of the left lung, which occurred at the Merchant Seamen's Hospital at

Hong Kong, under the care of Dr. W. Harland, of that hospital:—"An American sailor was brought up to the hospital in such a condition as almost to preclude all hope of his surviving beyond a few days. On the second day after his admission he fell out of bed, and on being raised up again he complained of severe pain under the left mamma. Dr. Harland immediately examined the part, and found a swelling of considerable size, and with distinct fluctuation. With some hesitation he made a small incision, and finding an escape of pus only, he enlarged the opening to about an inch and a half in length, when upwards of half a pint of extremely fetid pus, with small shreds of gangrened lung, were evacuated, the discharge being suddenly stopped by a mass of the dead lung itself protruding through the orifice. By gentle traction with the forceps he was enabled to withdraw this to the extent of nearly two inches; but finding it not yield any further, and afraid of hæmorrhage if he cut it, he applied a poultice, which was renewed every three or four hours, and at each dressing pulled out the lung a little more as the opening increased in size by ulcerative absorption. On the third day after the incision was made the protruding mass became so troublesome and offensive, besides exhibiting some appearance of spontaneous separation, that Dr. Harland removed it by the knife; no hæmorrhage occurred, and the opening appeared to be filled up by the pericardium (as by a valve), which gradually became thickened and adherent all round to the parietes of the chest. The detached piece of lung would scarcely go into a pint measure, and weighed nearly a pound. The man rapidly recovered, and about three months afterwards shipped again as a seaman, in a vessel bound to New York." Dr. Harland subsequently writes—"Last month (December, 1851), I was agreeably surprised by a visit from my old patient, who came to show me that he was alive, and quite strong and hearty again. It appears, that in consequence of the ulceration having exposed a part of one rib, some discharge continued to ooze from the wound for some months after he left me, and on which account he went into one of the hospitals on his arrival home in New York. Under medical treatment for a short time the wound soon healed, and his case excited considerable interest, almost all the principal medical men there having visited and examined him. From New York he went to sea again, and then to the mines in California, where he worked as a gold digger for above a year, and at last to Hong Kong, where he arrived last month. He told me he could work as well as ever, and had never been troubled with cough since he left me; the only difference he could perceive was, that he thought he was rather shorter-breathed than before, if he had to exert himself strongly for any length of time. A marked difference, too, is at once perceptible in the relative dimensions of the two sides of the chest. He went back to California a few days ago (Jan. 29, 1852)." Dr. Halley regretted that more particulars were not added in regard to the subsequent physical and auscultatory signs, but hoped at a future time to lay them before the Society; at the same time he thought the case so remarkable and unique as to be well worthy of their attention, even in its present form.

#### Mr. I. B. BROWN read a paper

##### ON A NEW MODE OF OPERATING FOR OVARIAN DROPSY,

consisting of the excision of a portion of the cyst, returning the remaining portion into the peritoneal cavity, and closing the wound by sutures, thus allowing any fresh fluid secreted by the remaining portion of the cyst to escape into the cavity of the abdomen, there to be taken up by absorption, and discharged by the kidneys. Mr. Brown said this method of treatment was suggested to his mind by reflecting upon the numerous cases on record, in which a spontaneous cure has occurred by an accidental rupture of the cyst, followed by a copious discharge of urine. This mode was not considered applicable to every case, nor was it the purpose of the author to lay down any absolute rules for its use, but simply to relate such facts as had come under his observation.

*Case 1.*—This case had been alluded to on a former occasion, and Mr. Brown now read the notes of the case as they were taken by Mr. Bullock, at St. Mary's Hospital, where the operation was performed. The woman, aged 47, was subject to prolapsus uteri, which Mr. Brown considered as presenting a sufficient objection to treating the case by pressure. The swelling first appeared rather on the left side, about nineteen years ago, but had increased rapidly during the last six months. The following was her condition on admission to St. Mary's Hospital, February 13, 1852:—Abdomen considerably enlarged, with shooting pains extending to the shoulders. Complete procidentia uteri, returned with difficulty. Percussion dull in front, resonant at the sides, less so on the left than the right; fluctuation very distinct, the integuments moving freely over the tumour.—Feb. 14th: Ordinary diet; porter, one pint; blue-pill, three grains; compound aloetic pill, four grains, every night, with saline diuretics.—March 6th: General health good; some fluid drawn from the cyst with a small trocar was quite clear, with only a trace of albumen and some chlorides.—10th: She was placed under the influence of chloroform, and an incision was made through the integuments, down to the linea alba, from an inch and a half below the umbilicus, extending four inches. The linea alba was then divided, afterwards the transversalis fascia, and finally the peritoneum; the cyst was then presented to view, and found to be free from adhesions. It was seized by a pair of forceps, a large trocar was introduced, drawing off about sixteen pints of fluid, leaving some fluid in the cyst, and then a piece of the cyst which appeared comparatively free from bloodvessels was excised. The external wound was closed by interrupted sutures, the ligatures including all the abdominal parietes except the peritoneum. She was ordered two grains of opium immediately, and one grain every three hours. A pad of wet lint was placed over the wound, and a broad bandage round the abdomen. Severe peritonitis ensued for the first five or six days, which was subdued completely by large and repeated bleedings from the arm, with calomel and opium. In eight days the abdominal tenderness had subsided, the abdomen became flaccid, and the urine passed exceeded in quantity the fluid swallowed.—By the 21st (eleven days after the operation), the remains of the cyst could be felt on the right side of the cicatrix, as a solid substance of an irregular form. On the 3rd of April, no increase of the abdomen could be discovered, and on the 6th she was discharged. Mr. Brown said he expected that the kidneys would continue to secrete more fluid than was drunk for some time, and that the cyst would ultimately become of an indurated, perhaps calcareous character, possessing less vitality, and incapable of secreting fluid. He should feel himself bound to report to the Society any return of the disease, although he did not anticipate a relapse.

*Case 2.*—In this case, which had been treated nine years ago by tapping, pressure, mercurials, and diuretics, so far successfully that no return of fluid took place for seven years, the abdomen had been gradually enlarging for the last two years, and the patient was anxious for a radical cure, and sanguine as to the result of the operation of excision of a portion of the cyst. She was previously prepared for the operation by a farinaceous and milk diet, avoiding stimulants, and keeping the bowels well open daily, under which treatment the size of the abdomen was materially reduced. The operation was performed on the 29th of March, 1852, in a manner similar to that related in Case 1. Nine pints of clear fluid were withdrawn, and a portion of the cyst excised. But it unfortunately happened that the peritoneal coat of the cyst was very vascular, and hæmorrhage ensued, which was not to be subdued by torsion of the vessels. As there were no adhesions, it was determined to remove the whole cyst. A double ligature having been tightly applied over the pedicle, which was attached to the left ovary, about an inch and a half broad, and containing one large bloodvessel, the pedicle was divided, the cyst removed, sutures applied, and over them a many-tailed bandage. The case did very well, no signs

of inflammation occurred, the ligature came away in four weeks, and on the day following the patient was in her drawing-room, convalescent. This case was related, as illustrating an important difficulty which might occur, rendering the removal of the whole cyst a safer practice than tying several bleeding vessels, and leaving the ligatures within the peritoneum, a source of much danger.

*Case 3.*—In this case the operation was performed in a similar manner to that detailed in Case 1. A portion of the cyst was excised, but a second large cyst was found, the fluid of which was evacuated, and the wound closed. An attack of inflammation ensued, which was successfully combated by bleeding, calomel, and opium, and the patient did well. The first cyst became collapsed, and could be easily felt beneath the walls of the abdomen; but the second cyst has frequently filled since; and now, sixteen months after the operation, it fills at a much slower rate, and the patient's health is much improved. Steady and firm pressure has been had recourse to after each tapping, to which Mr. Brown attributes mainly the slower filling of the cyst. This case was related to show another complication which might occur.

Mr. Brown concluded by expressing a hope that this operation may prove to be another successful method of treating this very troublesome disease.—*Lancet*.

#### ON PHAGEDÆNIC ULCERATIONS—RAPID RECOVERIES.

SARAH H—, aged 6, a strumous child of low powers, living in an unhealthy neighbourhood, near Newton Causeway, was admitted an out-patient on July 18th, with acute phagedænic ulceration of the side of the tongue, gums, and lips; it was of one week's duration, and was now spreading rapidly. Caustic was freely applied. Ten grains of chlorate of potash in water to be given three times a day, and the sore to be sponged frequently in the course of the day with a solution of nitrate of silver, three grains to the ounce. In a few days the phagedænic action was checked, and at the end of a fortnight healthy granulations were seen fast repairing the breach. Bark and soda were now substituted. On August 8th, the child was perfectly cured.

MARY C—, aged 3½, living at Bermondsey, was brought to the surgery on March 8th, with phagedænic ulceration of the gums and inner part of the lip. She had been ailing for nearly one week, but the ulceration commenced four days back, and was now extending very fast. Nitrate of silver freely applied. Ten grains of chlorate of potash in water three times daily. A solution of caustic (three grains to the ounce) to be used frequently, and a saline purge occasionally. March 20th. Quite well.

ELIZABETH C—, aged 3, a thin, spare child, living at Hackney, in a healthy neighbourhood, became an out-patient on January 24th, having extensive sloughing phagedænic ulceration of the bend of the thigh on the right side, which was of eight days' duration. She was also afflicted with worms. Ordered a stale-beer grounds poultice, ten grains of calomel and scammony powder immediately; also twelve grains of chlorate of potash in water three times a day, and to have some meat and porter daily. On the 26th, a great many ascarides had been expelled, the sore had improved in appearance, and the sloughs were separating. 31st. The phagedænic action was entirely checked, and the health much improved. To continue the medicine, and to have another dose of the powder; nitric acid lotion applied to the sore. Feb. 21st. Child presented perfectly well.

JANE J—, aged 20 months, a stout, healthy-looking child, brought up by hand, living in the Kent-road, in a tolerably healthy part. Had been ailing one week, was brought to the surgery with extensive, spreading, superficial ulceration of both labia and bend of the thigh on the right side, almost running into gangrene. This was accompanied with great œdema, and excessive pain and difficulty in micturition. Ordered stale-beer grounds poultice, nutritious diet, and ten grains of chlorate of potash in barley-water three times a day. This treatment

was pursued with speedy success, subduing the phagedænic tendency, and causing a healthy action to be set up in the ulcerating surface. In a few days a simple bread cataplasm was substituted, and at the end of three weeks the child was quite cured.

The above four cases fully prove the value of nitrate of silver in solution and stale-beer grounds as applications in phagedænic action; at the same time the effects of chlorate of potash must not be forgotten as an important agent in checking acute ulcerative spreading. — *Guy's Hospital Repts.*

#### REVIEWS AND NOTICES OF BOOKS.

**LECTURES ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.** By EDWARD WM. MURPHY, A.M., M.D., Professor of Midwifery, University College, London, &c. London. 1852. 8vo. pp. 616.

It is unnecessary to tell our readers who Dr. Murphy is; but they may not all, perhaps, be aware what he *was*, and we feel a pleasure in acquainting them that he was once an assistant in the Lying-in Hospital of this his native city; and there he acquired that fund of experience and of practical knowledge which has so materially contributed to his success as an accoucheur and as a teacher. We are told in the preface that these "lectures are published, in the hope of facilitating the task of the student, who is desirous of giving his attention to the principles and practice of midwifery." Now, we have no hesitation in saying that they contain a vast deal to recommend them to the practitioner, as well as to the student, of midwifery, and that the work will take rank amongst our best treatises upon the obstetric art. It consists of thirty-three lectures (each constituting a chapter) upon parturition and the diseases incidental to the state of childbed. We shall try and give, as far as our space will afford, a condensed analysis of the contents of these chapters, which, with occasional extracts, will enable our readers to form a tolerably correct opinion, both as to the matter and manner, of the merits of this volume. There may be some points of theory and practice on which we are opposed to Professor Murphy. These we shall freely comment on, and endeavour to imitate the excellent author in expressing our sentiments with a due regard to courtesy, no less than to candour.

In the first two lectures we have a minute and explicit account of the obstetric properties of the female pelvis, its measurements and those of the foetal head. Next follows a description of the varieties and deformities in the figure and capacity of the pelvis, together with the different instruments which have been ingeniously devised for ascertaining the dimensions of the pelvic cavity during life. Upon none of these does Dr. Murphy place any reliance, but he thinks that "the experienced accoucheur, from constant habit, when he passes the fingers or hand into the vagina, will form a very accurate estimate of the space in the pelvis;" and we believe that after all, such is the only trustworthy mode of obtaining this desirable information. If students and practitioners made it a rule to practise this trifling manipulation in every case, a great degree of tact would be acquired, and in any given example little difficulty or uncertainty would be felt in pronouncing upon the condition of the hard passages. In the division of labours, and of the stages of labour, Denman has been followed, and in our judgment deservedly so; as for all the purposes which a classification is intended to serve, we think his has never been surpassed, nor equalled. Upon the much disputed question of the muscularity of the os uteri, Dr. Murphy thus expresses himself:—

"The os uteri has been generally considered to possess

circular fibres, its action to resemble, in some degree, the sphincter muscles in other situations, and its dilatation to be the effect of their relaxation. The existence of these circular fibres at the os uteri has never been proved. Hunter could not demonstrate them; Sir C. Bell could not trace them out. If a sphincter muscle exist in that situation, why should not its fibres be as distinct and as easily made out as the sphincters of other hollow muscular viscera? Neither does the manner in which the os uteri dilate support this assertion. Its expansion is very gradual; it yields slowly to the power described, and does not resemble the comparatively sudden relaxation of a sphincter muscle. Were it similar, rapid labours (at least so far as the dilatation of the os uteri is concerned) would be the rule, not the exception. It would be incorrect, then, to attribute the resistance offered by the os uteri to muscular contraction. It seems more probable, that the firm, highly condensed tissue which forms the cervix of the virgin uterus, still retains, in its altered state, many of its original characters; that this tissue, although more unfolded, is still sufficiently compact and elastic to offer a great degree of resistance, and that its dilatation is effected by the incessantly repeated efforts of the uterus slowly overcoming and expanding it." (p. 48.)

This view of the structure of the os tincæ is as irreconcilable with some of the phenomena exhibited by the part, as the assumption of its being exclusively muscular is with others. For example, if the existence of muscular fibres be denied to the uterine orifice, how can we explain its sudden yielding after long-continued rigidity? or the still more common occurrence of its forcible contraction after complete dilatation, as in cases of encysted placenta, and of *inversio uteri* where powerful contraction of the cervix presents a most formidable barrier to the reposition of the organ? In fact, the functions of the cervix uteri can only be explained on the ground of its being composed of mixed contractile fibre and elastic tissue. That it possesses the latter, Dr. Murphy evidently proves; and that the former is also demonstrable in it, was affirmed by Jobert and other anatomists, and is plainly admitted by Hunter, when he says: "The cervix uteri, where the penniform rugæ are situated, had not such regular nor so large fasciculi as the rest of the uterus." But he, as well as Bell, sought for a *complete circular muscle*, and failed to find it. Indeed the reason why such a muscle should not exist is sufficiently obvious, and has been accurately pointed out by Dr. Tyler Smith: we shall quote his own words:—

"Before the commencement of labour in primiparæ, the os uteri is quite closed; while in parturition it is dilated to such an extent as to permit the passage of the foetal head—a mass whose shortest diameter is three inches and a half, making the line of the circle necessary for its passage nearly eleven inches. This is a dilatation far exceeding that required in the actions of any of the recognized sphincters, and we cannot but conceive that if completely circular fibres existed at the os uteri, rupture of the circle would be inevitable."

A knowledge of the direction which the peristaltic action of the uterus takes, is of considerable importance. Müller, Michaelis, and Wigand, all maintain that uterine contraction begins at the cervix, and extends upwards to the fundus and back again to the point of departure, and this theory has been very successfully applied by Michaelis to explain why prolapse of the cord and descent of the arms before the head of the child does not oftener occur. In opposition to these eminent authorities, Professor Murphy asserts that the contraction of the womb commences at the fundus, and in support of his opinion, states that if the hand be introduced into the uterus after delivery, the contraction of the organ may be felt beginning at the fundus and travelling downwards. The rest of his argument is given in the following passage:—

"Now, if we desired an additional evidence to prove that the fundus was the first part of the uterus to contract, and not the

os uteri, we could not have a stronger proof than that advanced by Wigand to support a contrary opinion—viz., the head, when the contractions commence, getting 'even out of reach of the fingers, whilst the os uteri is filled with the bladder of membranes.' In Wigand's explanation, the influence of fluid pressure seems to be altogether forgotten. The immediate effect of contraction commencing at the fundus would be to compress the liquor amnii which of necessity forces its way before the head, on to the mouth of the uterus. The fluid in this position reacts against the head with the same power that it is compressed, and therefore pushes it up until the increasing contraction of the fundus forces the head down again, so that you perceive that the phenomena quoted are quite consistent with the statement that uterine contraction begins at the fundus; in fact, it could not be otherwise, so long as the waters remain in the uterus. But if the contraction commenced from below, the fluid must be driven upwards towards the fundus, and that portion between the os uteri and head pressed aside, at least in the first instance, so that the head might be easily felt when the pain commences, although not so afterwards; but the reverse is the case, and you will find that in those cases where the liquor amnii is in large quantity, that it is difficult to feel the head at all, except in the interval of the pains." (p. 52.)

The arguments advanced in this passage do not affect the opinion of Wigand, as we decidedly think Dr. Murphy miscalculates the effect of fluid pressure. Dr. Tyler Smith has exposed this error in language so clear and convincing that we make no apology for transcribing his strictures upon it:—

"It is a well-known law in hydrostatics, that when fluid is subjected to compression, the effect is equally diffused through the whole mass, and is felt alike in all directions. Pressure upon the os uteri, in contractions of this part, does not affect that portion of fluid contained in the cervix more than that in the fundus. Pressure applied at any part of the uterus would as inevitably protrude, in the first instance, the membranes through the open os uteri, as that pressure on any part of a bladder of water with a hole in the neck would expel the fluid. It would not matter whether the pressure were exerted close to the aperture or at the fundus of the bladder. Thus, then, this part of the argument of Dr. Murphy falls to the ground. . . . Neither is it correct to say, that fluid pressure coming from the fundus would react against the head of the fœtus at the cervix. The recession, more apparent than real, of the head at the commencement of a pain, is undoubtedly in favour of the view of Wigand. A solid body, such as the fœtus, might be moved in a fluid medium by solid pressure applied at any particular part; and the contraction commencing at the cervix, the uterus comes into immediate contact with the head, and moves it in the fluid medium, as it is moved upwards in the ballottement; the fluid must present by just so much as the uterine cavity had been diminished by the contraction, and it would be only where the fundus contracted, so as to come in contact with the solid fœtus, that the head would descend and displace the waters."

For ourselves we must be permitted to say, that repeated observation has corroborated the facts described by Wigand, from which he has, correctly we think, deduced his view regarding the direction of the uterine contraction.

Lectures four, five, and six are occupied in describing the phenomena and management of natural labour. They are replete with sound practical instruction, and supply information of a kind peculiarly suited to the wants and difficulties of the accoucheur on his first entrance into private practice. The hints given by the author for regulating the attendant's conduct and deportment, towards the patient and her friends, are particularly just and applicable. Every one who has had much professional intercourse with the better classes of society will acknowledge the propriety and the excellence of the advice contained in the following remarks:—

"If it be a first pregnancy that you are summoned to, it is advisable that your introduction be not too abrupt: caution in this respect is of still greater importance if called to a patient to whom you had not previously been introduced; the mere

circumstance of a stranger entering the apartment of a parturient woman has caused a total suspension of her labour. Some preparation, in the way of announcement, is therefore necessary. For the same reason it would be prudent, when introduced, to direct your patient's attention as much as possible from contemplating the character in which you appear before her, to draw her away from the subject that brought you there, and to lead her to forget the part that you have to fulfil. You would not therefore catechise her too strictly about herself, or remind her of what is going to happen by too busy a display of preparation. A few minutes conversation with the nurse is generally sufficient to learn every particular of importance; but your patient should only receive from you the words of comfort and encouragement. The nurse, however, does not require the same forbearance. It will be your duty to ascertain from her every point upon which you desire to be satisfied. When the pains commenced? Their character? If accompanied by much, or by little excitement? The state of the bowels, and whether the bladder has been relieved? If your patient has any constitutional peculiarity? You should also examine the bandage, pins, ligature, and every trifling matter which might inconvenience you, if not prepared according to your views." (p. 80.)

This is all most excellent advice and well deserves to be attentively studied by the junior practitioner, for whose benefit we here introduce the passage. Part of it reminds us of Smellie's description of some of the qualifications which should go to form an accoucheur: "Over and above the advantages of education he ought to be endued with a natural sagacity, resolution, and prudence; together with that humanity which adorns the owner, and never fails of being agreeable to the distressed patient; in consequence of this virtue he will assist the poor as well as the rich, behaving always with charity and compassion. He ought to act and speak with the utmost delicacy of decorum, and never violate the trust reposed in him, so as to harbour the least immoral or indecent design; but demean himself in all respects suitable to the dignity of his profession."

The seventh lecture opens with the great subject of Difficult Labour, the consideration of which, with all the topics arising out of it, fills some 120 pages of the book. Of this numerous class, Dr. Murphy makes two divisions; the *first*, including cases in which labour is merely prolonged beyond the average period without being at any time unusually severe; this is called *tedious labour*: and the *second* comprehends those cases where, without reference to time, there is a powerful struggle carried on by the uterus to overcome some unusual resistance; and this is appropriately termed *laborious labour*. Although his definitions of these are in some respects faulty, still this general division is a useful and convenient one, and is nearly tantamount to arranging difficult labours under two heads, according as the delay takes place in the first or second stage of labour: a distinction of immense practical importance, and one to which Dr. Churchill was the first to draw particular attention. Still following our author, we find that *tedious* labour may depend on inefficient action of the uterus, or rigidity of the passages. For the production of the former, five causes are assigned—viz., over-distension of the uterus, extreme obliquity of the uterus, gradual escape of the liquor amnii, hysterical excitement, and mental despondency. Under each of these heads appropriate observations are given, especially with reference to the treatment. Denman, in his enumeration of the causes of inert uterine action, assigns "dribbling of the waters" as one; but, even though backed by so high an authority, we think our author might have omitted it. How the mere circumstance of the escape of the liquor amnii being gradual can produce uterine inertia, we never could comprehend; unless it be, that what is *retained* affects the uterus by dis-

tending it; in which case this cause might be included under the head of "over-distension of the uterus." "Dribbling of the waters" being thus disposed of, we would substitute in its room the eighth of Denman's ten causes—viz., "want of irritability in the constitution," as instances undoubtedly do occur where no other reason can possibly be discovered or assigned for the languid action of the womb. Of rigidity of the cervix uteri, four or five varieties are described, differing according to the sensible qualities of the part. These distinctions appear rather artificial, and do not afford sufficient or trustworthy indications of treatment. When there exists an inflammatory condition of the os uteri, Dr. Murphy says that "local depletion, either by leeches or by scarification, may be employed with advantage, and when the pains cease the head should be pressed back towards the brim, to relieve the constriction of the cervix uteri." The artificial abstraction of blood from the os uteri, or the pressing backwards of the fetal head, are two remedies for rigidity of this part that we have never seen put in practice. The latter is decidedly objectionable; and the cases must be very rare indeed where the former should be preferred to the established modes of treatment.

We are surprised to find no mention made of the use of the warm-bath in obstinate cases of undilatable os uteri. In several cases we have seen it act most happily and expeditiously in producing relaxation of this orifice; and, if we mistake not, Drs. Hardy and McClintock record in their "Midwifery" some cases of an equally satisfactory kind. The warm hip-bath is much employed on the Continent for the same purpose, and we feel convinced it would prove a valuable auxiliary, as it is free from some of the objections which apply to the general warm-bath. Our author has the boldness to avow that he should be disposed to incise the os uteri, and give the child a chance of escape, in cases of insuperable rigidity, and where there is only a choice between this alternative and perforation; but then he qualifies this statement by the candid admission that "this is but an individual opinion, and needs support." Now, we do not deny but that a practitioner might be called to a patient in whom, through previous mismanagement or neglect, this intractable state of the os tincæ has been induced, and at the same time symptoms are present which forbid delay, and the child is yet alive. Under such a combination of circumstances, the proposal might perhaps have some claim to consideration; but we confidently maintain that where a patient has been from the beginning of her labour under the direction of a prudent and judicious practitioner—one, for example, of Dr. Murphy's stamp or training—difficulties of so formidable and conflicting a nature will not arise once in two thousand cases; and still more rarely will the child be alive when such a critical moment has arrived.

The most common cases of the *laborious* class are those where the head, after entering the pelvis, is retarded in its progress through it. The cause of delay here may be from simple *arrest*, or from *impaction*, of the head. In a practical point of view, the distinction between these is of great consequence, and is clearly indicated by our author:—

"The term *arrest* is applied to those cases where, although the head ceases to advance, the cause either does not depend upon disproportion in the pelvis, or, when disproportion exists, it is not so great as to render the delivery of a living child impossible. . . . The term *impaction* is employed when the head not only ceases to advance, but when there is every evidence that its further progress is beyond the power of the uterus. The use of this term is therefore confined to

those cases in which there is great deformity in the pelvis, or to those in which a very large and ossified head is wedged in the deep narrow cavity of the masculine pelvis. When the head is *arrested* in the pelvic cavity, it may be readily distinguished from the *impacted* head. In the former case, if the head be slightly pushed back, the finger can be passed with facility between the head and the pelvis, the ear may be touched, the parietal bones do not overlap each other strongly, the scalp is only puckered, or, if a tumour be formed on the presenting part, it is diffused, increases slowly, and seldom attains any magnitude. In the latter instance, when the head is impacted, it cannot be so easily displaced; it is impossible without force to pass the finger between it and the symphysis pubis; the ear cannot be felt, and the urethra is compressed. The parietal bones are strongly overlapped, and cause the sensation to the finger that is expressed by the homely simile of 'the sow's back'; a tumour grows very rapidly, and to a great size, often completely obscuring the character of the presentation; the vagina is also swollen and congested. If, however, the death of the child takes place, it becomes less in size, softer and crepitant, and oedematous, while the serrated edge of the suture may be felt still more distinctly." (p. 133.)

The whole subject of *laborious* labours is discussed at considerable length, and with much minuteness, in this and the five following lectures. Indeed, upon their preparation, Dr. Murphy seems to have bestowed great pains and research; and deservedly so, as the matters to which they relate are of paramount importance. We were surprised at not being able to find here any allusion to the proposal of turning the child in cases of slight deformity of the pelvis: a practice which was long ago suggested by Sir Fielding Ould, and has since been recommended by several continental accoucheurs of great eminence, and more recently by Professor Simpson of Edinburgh. The description of the various instruments used and recommended, together with the different obstetric operations, are clear and comprehensive, and the principles enunciated must lead to sound practical deductions. The arguments for and against delay in cases of arrest of the head, or when it very slowly advances, are fully and honestly given; and the whole of this much controverted question is handled with judgment and ability. In the form of aphorisms (eighty-four in number), Dr. Murphy has embodied the practical rules and precepts of the lectures upon natural and difficult parturition. They are, to be sure, all excellent in themselves, and form a respectable code of maxims; but they would be of more utility if published separately, as no one would take the trouble of reading them when the same book contained the admirable observations of which they are only the dried concentrated extract.

In lectures 14 and 15, preternatural labours receive a proper share of attention, and with lecture 16 we enter upon complex labours, the first division of which that comes under notice is hæmorrhage. This leads him in the first instance to review the manner in which hæmorrhages takes place from other parts of the body, and to point out the principles upon which are founded the different means employed to arrest them. The vascular arrangement and physiology of the uterus and placenta are next examined, and the nature of the union between the two is very clearly described. The natural agents and therapeutic remedies for the arrest of hæmorrhage are then enumerated, and their respective influence and utility set forth. Amongst the latter group, opium very properly holds a place, and the remarks upon it are not only original, but they contain much point and application:—

"The paradox has been proposed: How can opium cause the uterus to contract in hæmorrhages, and to relax in other cases; for instance, when given for this purpose in arm-presentation? The same medicine cannot produce opposite

effects on the same structure. In this query, the condition of the nervous system, a most essential element, is totally overlooked, and the influence of opium, when nervous irritability is almost exhausted, is compared with its effects when the same power is excited to the greatest degree. It is assumed that the operation of opium must be the same when the uterus has lost all power to contract, and when it is contracted spasmodically. The question, therefore, might easily be answered, by stating that opium is both a stimulant and a sedative, and that one effect or the other is produced, according to the relation existing between the nervous energy of the uterus and the dose of the medicine given. If nervous irritability be not impaired, or if it be increased, a very small dose of opium would stimulate: a larger one would exhibit its sedative effects. But if, on the contrary, that irritability is destroyed and the uterus atonic, the same large dose would only act as a stimulant; nor will the sedative property of the medicine be observed until the nervous energy is restored." (p. 317.)

Every one is aware of the protracted controversy which, until very lately, was carried on touching the treatment of certain cases of placenta prævia; some men strictly adhering to the practice of Rigby, and others advocating a serious innovation upon it—namely, to destroy the connexion between the placenta and uterus, and leave the child to be expelled by Nature, or turned at a later period. In the consideration of this question our author displays much commendable anxiety to arrive at its true solution; and as it is really one of great practical importance, we just quote the general conclusions he comes to:—

"1st. In a case where no exhaustion has taken place, or where it is but commencing, to turn and deliver the child the moment the os uteri is sufficiently dilated. If it be dilatate (and this is generally the case), you may pass through it, although it be not larger than a crown-piece. If it be not so, by properly compressing the placenta, and using other means to support the circulation, you will prevent exhaustion increasing until you can deliver the patient.

2nd. In a case of extreme exhaustion, with frequent fainting, fluttering pulse, rapid, laboured, perhaps stertorous, respiration, blowing of the cheeks, jactitation, incoherent, and general pallor and coldness of the surface, do not attempt to turn the child; rather separate the placenta, and leave the child undisturbed until some decided reaction takes place. I am aware that this rule is a direct infringement on the principle of those who look with horror on the risk of allowing a woman to die undelivered. It appears to me to be the only chance of preventing her death.

3rd. When the os uteri is rigid, use every means to compress the placenta, and to increase the action of the uterus, so as to give it time to dilate, and to enable you to turn; but if hæmorrhage so increase as to cause a dangerous degree of exhaustion, separate the placenta, rather than force your hand and arm into the uterus." (p. 354)

With this extract we must reluctantly take leave of Professor Murphy. Already we have far exceeded our limits, and yet, more than one-third of the lectures have not been touched upon. But this, in itself, constitutes the strongest mark of our approval of their contents. By this work, Dr. Murphy has placed his reputation and his fame on a solid and durable foundation. It has, no doubt, some blemishes and a few defects, but these are but light when weighed in the same balance with the comprehensiveness, the candour, and the good sense which are everywhere conspicuous in its pages.

**CAUTERIZATION OF THE GLOTTIS IN WHOOPING COUGH.**—M. Jobert has published the results of his experience of this mode of treating whooping cough. He has treated in all 98 cases in this manner, but he excludes 30 of these as not being worthy of notice. The remaining 68 cases he divided into three series, according to the period at which the treatment was commenced. Of these, the general results were, that in 40 the cure was rapidly effected, in 21 a marked relief was experienced, and in seven cases only the treatment failed altogether.—*Lancet*, 1874.

## MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE members of this Society held their tenth annual meeting on Monday, the 7th inst., in the Hall of the College of Physicians.

Dr. MONTGOMERY, President of the College, in the chair.

The CHAIRMAN said it appeared to him that the first subject on which he ought to enter, was congratulation that they should have present at the meeting so large a number of gentlemen who had come from great distances in the country to give their countenance and support to the society. As president of this meeting, he begged to tender them his warmest acknowledgments. The report of the previous year's proceedings would presently be read, from which the meeting would learn with satisfaction that the amount of subscriptions received during that period was greater than that contributed in any former year, with the exception of that immediately preceding, which it fully equalled in amount; while at the same time there had been considerable donations, which was a matter of great importance, inasmuch as those donations would remain funded capital to the society, and consequently ensure an annual increase of income, which nothing could diminish. With the subscriptions, of course the case was otherwise. The report would also give information to the meeting of the success of the branch associations throughout the country, which was also a matter to be rejoiced at. He very much regretted that those cheering considerations should be clouded by any one circumstance connected with the history of the past year; but it was well known to those present that their late excellent treasurer had been removed from amongst them, leaving them, he might say, one and all—whether as members of that society or as individuals—distressed and disheartened by his loss. He was certain that his highest eulogy was written in the hearts of those who knew him best during life: but after many years of close intimacy with that individual, in which he (the chairman) received many kindnesses at his hands, for his own part he felt that the "heart's abundance" ought to be uttered in words. The name of Maurice Collis was inseparably united with the institution of that society, and those who were earliest connected with it would remember the great efforts he made in the earliest struggles for its establishment (hear.) He (the chairman) had reason to know that the prosperity of their institution was a cherished hope with him to the latest hour of his life. Benevolence with him was not a passing sentiment, but an abiding, heartfelt principle of action, under whose influence his greatest pleasure lay in doing good to others. Hence it was that in the halloved circle of domestic life he was almost idolized, whilst amongst the public he was esteemed, respected, and honoured. The chairman then called upon the secretary to read the report.

The SECRETARY (Dr. Benson) read the following

### REPORT.

It is with mingled feelings of satisfaction and regret that the committee of the Medical Benevolent Society of Ireland now present to its friends and subscribers their tenth annual report. They are thankful that the hopes of its founders have been in a great measure realised, and their fears removed; but at the same time they have to lament the apathy with which some members of the profession still look on at the destitution of their brethren, and at the misery and distress of widows and orphans for whom they ought to feel deeply interested.

The subscriptions during the past year have equalled those of the preceding year, and exceeded those of any former one. The donations are not large, yet they are encouraging, as derived in part from non-professional men. From Arthur Guinness, Esq., the sum of £25 has been received, and from John Purser, Esq., £10, in addition to his former gift of £15. These donations, generously and without solicitation, bestowed by men of such known benevolence and judgment, may be considered a gratifying acknowledgment of the value of our society, and of the claims which our profession has upon the gratitude of the public, and ought to cheer us on in the good work in which we are engaged.

Dr. Macdonnell, on accepting the office of Poor-law Commissioner, not only doubled his annual subscription, but also gave a donation of £25; and some other donations of smaller amount have been received, as will be stated by the treasurer. These have been added to your funded capital, which now exceeds £3000. It is a rule of the society, as you are aware, that only the interest of these donations shall be distributed annually, along with the subscriptions; every such addition therefore increases the stability of our institution, and permanently enlarges its means of usefulness.

The subscriptions, as already stated, have equalled those of the preceding year, but they have differed from them in different places. Armagh, Belfast, Newry, and Waterford, have contributed more than formerly; Dublin something less, and Cork considerably less. The interest of the funded reserve has, of course, increased, and you are therefore in a position to give away about as much as last year, and much more than on any former occasion.

So much, in general terms, for the resources of the institution. The details will be shown in the treasurer's statement of accounts.

The claims on the society this year have been greater than at any former period. Forty-eight families have been considered fit objects for the exercise of your benevolence—the greatest number before was forty-five. These families consisted of three medical men with their wives and children, thirty-nine widows, and one hundred and fifty-two orphans, eighteen of whom have neither father nor mother. Twelve of the families had not received relief before. Of the medical men, one is a Fellow of the King and Queen's College of Physicians; one an M.D. of Glasgow, recommended by the Armagh Branch; and the third is a member of the London College of Surgeons. To this last gentleman's case the attention of the society was directed last year. He resides in a remote and impoverished part of the country, where his very limited income, greatly reduced by protracted illness, scarcely supplied with necessaries his large family, consisting of seven children, two grandchildren, and a widowed sister. He had effected an insurance on his life for £500 many years ago, but last year he was rendered, by continued ill-health, totally unable to pay the premium. The provision which he had prudently made for his family was therefore in danger of being lost, but was saved for that time by your generous interposition; the premium amounting to £13 18s. 9d. having been paid to the office on his behalf. This year the difficulties of his situation seemed aggravated. His health was unimproved, and his salary from a dispensary, almost his only means of subsistence, lost for several months by the changes in the medical charities, and then lowered. All hope of keeping up the insurance from his own resources was thus taken away for the present; and after minute inquiry into the facts of the case, from undoubted authority, the premium was paid for this year also.

Nothing can be more legitimate than such an expenditure of your money. The society was formed chiefly, as the third fundamental rule declares, "for the relief of medical men under severe and urgent distress, occasioned by sickness, accident, or any other calamity;" and perhaps no better proof could be given of the beneficial working of such a society as this, so much of permanent good having been effected by so small a sum. But, of course, there is need of caution in such cases, and close examination into particulars, lest any person should be induced to lean too much on extraneous aid, and lose his self-respect and self-reliance.

Most of the recipients of your bounty now are widows and orphans. This unfortunately has arisen from the occurrence of so many premature deaths among the members of our profession, and the absence of a proper spirit of economy and forethought. But every report of this society brings prominently forward the duty and the necessity of making some provision, and reiterates the recommendation to do so. Thus, it is hoped, that, by constant repetition, much good will be effected.

The case just mentioned, however, serves to answer an excuse sometimes made by persons when asked to subscribe to this society. They say that every man ought to insure his life if he have no certain income already secured, and if so, there would be no such destitution of widows and orphans as we see. But even if so desirable a thing were done, and that every man in the profession had his life insured, there would still, it is too plain, be ample room for the operations of this society, though the persons receiving your aid would oftener be the medical men themselves, not their bereaved families.

The aid afforded by this society is found to be of incalculable

importance. Although the sums granted are small, varying from £4 to £15, they bear, in all instances, a considerable proportion to the very limited incomes of those to whom they are given, and the most grateful expressions in return mark the feelings of the individuals who receive them. But in no case are they such as could justify a man in leaving his family dependent on them, or at all encourage him in the folly or wickedness of neglecting to make a proper provision, as far as in him lay, against the sad consequence of his illness or death.

Amongst the suppliants for your bounty this year, as on former occasions, are found the children and widows of men who held the highest rank in both branches of the profession, and often have members of the committee exclaimed with astonishment on seeing the names of men whose station, when alive, seemed high enough to place their surviving families beyond the reach of want. But such is the fact; and oh! that it would read a lesson to those who now enjoy a competency; that it would induce them to make a provision for their families by insurance, or otherwise, while they have the power, and also lead them to feel compassion for the misfortunes of others.

Regard for the feelings of individuals prevents the committee from naming those who received assistance, or even from specifying their residence; but a registry of every case is kept in the large book on the table, which is open to the inspection of every member. It will be there seen that a searching inquiry has been made into all the circumstances of the applicants—their names, ages, and residence; the name, age, and residence of the father or husband on whose account they found their claim; the degree or diploma which he held; the time and cause of his death, or the cause and nature of his distress if he be living; the appointments which he held; the sources of his income; whether he subscribed to this fund or not; the present condition of the applicant; the number, names, and ages of the children; the means of support which they possess; the assistance given by friends; the expectations from friends; and the references to members who can vouch for the statements. All these points are noted down after suitable investigation, and thus a most valuable statistical record is preserved, and means afforded for every member to judge of the merits of each case. It has been the earnest desire and endeavour of your committee to apportion the grants to the urgency of each case with all the impartiality of which they are capable. They have weighed the helplessness as well as the number in each family; they have searched into their expectations; the claims they had on others, and the reasonableness of such claims; and, after a long and patient consideration, they have come to the conclusions recorded in this registry, and which they confidently submit to your approval.

Your committee have to congratulate you on the efficient working of the branch associations during the past year, and on the formation of a new one—namely, at Waterford. The importance of such associations in collecting funds, in keeping up an interest in the prosperity of the parent society, in securing the faithful distribution of money in their localities, in procuring accurate information as to the real wants of the applicants, and in many other ways, is very considerable. Commenced, too, in the kindly feelings of charity, and of sympathy with the wants and sufferings of their professional brethren, they would prove a bond of union amongst the members of that profession, and conduce to that harmony and social intercourse, and good understanding, from which the best results might be expected. It is to be regretted that several large towns still remain without a branch, as Limerick, Galway, Sligo, Derry, Drogheda, Kilkenny, Clonmel, &c.

Two years ago the committee had to record the melancholy death of a most esteemed and generous benefactor, Mr. Carmichael, whose noble gift of £500, and his bequest of £4,500 in reversion, has contributed so largely to the stability and efficiency of the institution.

Last year the committee had to regret the loss of another valued friend, Dr. Kidd, who took an early interest in this charity, and advanced it much by his personal exertions and influence.

This year has brought with it another serious calamity in the lamented death of our late treasurer, Maurice Collis, Esq. This most estimable and benevolent man had been treasurer to this society since its foundation. He had devoted a great deal of time, and thought, and labour to the advancement of its interests; and while his uprightness added much to the respect and confidence which this society has acquired, his amiable and truly Christian spirit, espe-

cially towards the applicants for your assistance, greatly enhanced the benefits which it has been enabled to confer, or softened the disappointments which were sometimes unavoidable.

But while we mourn over the loss of these early, and generous, and powerful friends, let us not be discouraged; let us rather be stimulated to renewed exertion; let us rise with our responsibilities; let us imitate their noble example as far as in us lies, and endeavour, with God's blessing, to carry on this good work with unimpaired efficiency.

Dr. J. F. DUNCAN, as successor to the office of treasurer, in the room of the late Dr. Collis, thought it but due to his predecessor to say that, on his papers and accounts being handed over to him, he found that they had been kept with extreme simplicity and accuracy, and that the last entry in his book was a record of his subscription for the current year, under which he had drawn a line with his own hand, totted up the amount with scrupulous fidelity, and then handed a cheque for the balance due to the society. With such perfect composure and such complete self-possession did he arrange his affairs in the prospect of the great change which he felt to be approaching. He remarked upon the economy with which the objects of the society were carried out, nothing having been paid for rent of office, nothing for an assistant-secretary, or even a clerk; in fact, the only sum paid in the shape of recompense for services rendered was the trifling sum of £2 5s. charged as poundage to the collector. He stated that having had an intimate acquaintance with the working of various charitable institutions, he felt bound to state that in none of them was the same amount of work discharged at so little cost to the charity, and that the subscribers to the fund had the satisfaction of knowing that anything they did contribute to its funds was fully and accurately applied to the purpose for which it was intended. In conclusion, he remarked upon the fair and impartial manner in which the distribution of the funds was conducted by the committee, every member of which seemed to be actuated by the single sentiment of acting fairly by all the claimants, without reference to friendship, interest, or locality.

Sir HENRY MARSH, Bart., rose and said, he had the honour to propose the first resolution, to the effect—

That the report just read should be received and adopted, printed, and circulated (together with the treasurer's statement of accounts) amongst the members of the profession at large.

He said he had heard with much pleasure the subject-matter of the report. It was one of great interest, full in all its statements and details, and in every respect satisfactory. One of the facts therein stated he had heard with peculiar interest; he alluded to that which afforded to a medical practitioner, incapacitated by continued ill-health from the discharge of his professional duties, the means of maintaining and preserving the policy of insurance on which the future support of his family depended. But for the allocation of a portion of the funds of this society to this useful object, the family would be left in utter destitution. How much would this have aggravated the sufferings of a sick father, no longer able to work for the support of his children! Under ordinary circumstances, such a thing of course ought not to be done. Under the peculiar and distressing circumstances detailed in the report, must it not be most gratifying to every member of the society, to all who feel a deep interest in its prosperity, to know that when a brother practitioner is (not from any fault of his own) unable to support his family, unable to make any provision for those he may leave after him, that the power is vested in this society to stretch forth a friendly and fostering hand to rescue them from the depths and miseries of penury. In fact, he (Sir H. Marsh) did not know of any society in which the principles of kindness and humanity, without any, even the least admixture of selfishness, were more prominently and more characteristically exhibited than in the Medical Benevolent Fund Society; and he was glad to find that its supporters and contributors were not restricted to the members of the medical profession. Some of the kind hearted who move in another and different

sphere of life have generously enrolled their names. It is to be hoped that the practical utility of this society, when still more generally known, will lead others to follow their excellent example. Earnestly, too, it is to be hoped, that every member of the profession will join heart and hand in giving a cordial support to this valuable institution; and that after no long time the name of not one medical gentleman throughout the length and breadth of the land will be found wanting in the list of contributors. If every man will read this report, and reflect upon the good which has been done, and the still greater good which may yet be done, he will, it is ardently to be hoped, contribute even a small annual sum. Were the whole medical body thus to act unitedly and cordially, there is no doubt but that this society would take deep root, would spread its branches far and wide, and receive under its shelter many a destitute widow and many a destitute orphan. All are painfully aware of the havoc which during late years contagious disease has made amongst the members of a profession fearlessly and nobly devoted to the hazardous work of saving human life; many, very many, most deservedly esteemed and lamented, have fallen in the ranks, have died in the service of their country, and that too at so early a period of life that a provision for their families could not have been made. The late destructive epidemics have, indeed, swept away very many members of the medical profession who laboured day and night to stem the fatal torrent; and surely it is most gratifying to think that a society does exist, one of the objects of which is to afford aid and support to widows and orphans who had been otherwise left wholly unprovided for. These, and other considerations of a purely beneficent nature, will (one cannot doubt it) induce the whole body of the medical profession in Ireland to support this valuable, benevolent, and unselfish society.

Dr. BRUNKER of Dundalk said he had great pleasure in seconding the resolution, which passed unanimously.

Dr. STOKES proposed the second resolution:—

That the necessity for the existence of a society like ours becomes every year more apparent, and that therefore every member of the profession be earnestly requested to give it pecuniary assistance.

He said it was scarcely possible to frame a resolution of greater importance than the one he had just read. It called upon all their medical brethren to assist in the forwarding of the objects of their society, the nature of which had been fully set forth in the report, and commented upon in the eloquent observations of Sir Henry Marsh. There could be no question whatever that the circumstances which led to the necessity of the society implied that the profession in this country was not a very wealthy one, as had been previously observed. So many calamitous circumstances had occurred to reduce the means of the working members of the profession as to render it at first sight not at all wonderful that such should be the case; still he confessed it was his opinion that the profession in Ireland had not as yet responded to the call that had been made on them in a manner worthy of themselves. He said this with very great regret, but he felt it to be his deep conviction. It might be said that they had not been sufficiently pressed. Considering the great labours of their worthy secretary, he thought it would not be out of order to observe that, in his opinion, nothing would be more likely to increase the funds of the society than to appropriate a portion of these funds to the payment of an intelligent and active clerk, who would keep up a continuous correspondence, not only amongst the medical profession in Ireland, but also with their medical brethren in England, a great many of whom he was satisfied would not only subscribe themselves, but become the centres of branch associations in various parts of that country, for their assistance.

Dr. SHEKLETON seconded the resolution, and it was carried unanimously.

Dr. NELIGAN proposed the third resolution:—

That having before us the melancholy consequences which result from the premature deaths of medical men, we earnestly

entreat practitioners every where to insure their lives (if they have not otherwise made provision for their families) as a duty which they owe to themselves, to their profession, and to society.

He remarked that the principle contained in it—namely, the benefits derivable from life assurance, was admitted by all, and required no comment from him; examples of the incalculable advantages it so often conferred on the bereaved widow and orphan children were but too common, and many such must be within the experience of his hearers. He considered that the members of the society might well congratulate themselves on the report which had that day been read. In times of difficulty and distress, which especially bore heavily on the medical profession, and moreover during a year in which the country practitioners were exposed to all the difficulties, uncertainties, and in numerous instances, pecuniary losses, attendant on the changes incident to the alteration in the arrangements of the medical charities which had just taken place, it was gratifying to find that the total amount of money received in subscriptions had not fallen off; in some districts, it was true, there was a diminution, but in others there was sufficient increase to more than counterbalance this loss. It was objected by some, and the remark had been made to him (Dr. Neligan), that this society conferred no especial benefits on those contributors to its funds—that the subscribers and donors to it had no greater claim to receive relief for themselves or their families, should they require it, than those who never advanced it by either their money or their time. Now, this he regarded as perhaps the most valuable of its fundamental laws, embodying the true principle of benevolence and charity: in relieving others its members sought not aught for themselves. To such objectors he would say, if you will not aid us during your life, at least spare us the necessity of providing for your families after your death by complying with the entreaty contained in the resolution he had now the honour to propose.

Dr. BOXWELL of Wexford had great pleasure in seconding the resolution, which then passed unanimously.

Dr. ROE of Cavan proposed the fourth resolution:—

That the local committees in Belfast, Armagh, Cork, and Newry, and in particular the secretaries of these branches, deserve our warmest acknowledgments for the zeal and success with which they performed the duties that devolved upon them during the past year.

He observed, I do feel, Mr. President, that the local committees mentioned in this resolution deserve your warm thanks, because I am aware of the great difficulty, almost universally felt throughout this country, in collecting or obtaining any contributions for any society or institution however meritorious or deserving support. I feel in it also a certain degree of reproof to myself for not having carried out my promise to the society at its last anniversary meeting of rendering it more aid and assistance than I have been enabled to do; for notwithstanding my best efforts, I was enabled to add only six names to my own, making in all a sum not amounting to £6, while I find the generosity and liberality of your society has extended its nobly benevolent help to three applicants from my county. It gives me great pleasure to hear the cause of universal and general support so ably advocated by Dr. Stokes; for I well remember at your last anniversary meeting, when our late excellent and truly valuable treasurer, whom I feel proud in calling my old and early friend, and whose loss I am sure, in common with every member of this society, our profession has to deplore, I say I well remember the sharpness as well as the power with which he (Mr. Collis) rebuked the apathy of many members of the profession, even in this great city, who, while “rolling in wealth and affluence, many of them in their carriages, would not contribute to the relief of their distressed brethren, or their afflicted widows and orphans.” Dr. Stokes then observed it was useless to find fault, but let us all individually and collectively endeavour to do more, and better, in future; to promote and establish the excellent and benevolent cause we have in hand. I will again promise

to do my very best to forward the objects of your noble society, and although our contributions cannot be large or liberal, yet I will exert all my power to create an interest for the society, and I am sure you will take the will for the deed when you know what strugglers we poor country medical folk are. As I see beside me several of my respected country medical friends, I would take the liberty which this opportunity affords me of suggesting to them the formation of County Medical Associations for the protection of their own rights and privileges, and at the same time instituting small branch associations for the support of our good Medical Benevolent Fund Society.

Dr. MACDONNELL, Poor-law Commissioner, said he had great pleasure in seconding the resolution. The branch committees, he thought, had done their duty well, and were well deserving of the thanks of the society. The perfect confidence and good understanding that had been maintained between them and the central committee had contributed greatly to the prosperity and well-working of the society. He had only to regret that the branch associations were not more numerous. He thought it not creditable to the profession that there should be any large town in Ireland without one. He regretted much that the earnest efforts of their friend (Dr. Roe) to form such an association in Cavan had not been successful; but he thought that if Dr. Roe had endeavoured to lower the tone of professional pride in the matter of subscriptions, he would have had greater success. If every member of the profession gave, “not grudgingly or of necessity,” what he could give without the least inconvenience, the funds and usefulness of their excellent charity would be much more than doubled.

Dr. BENSON begged to remark, in connexion with the observations just made, that probably a very large sum might be collected throughout Ireland if the friends of the society would take *collecting cards*, and ask small sums from those who might be unable or unwilling to give larger contributions. He revived this suggestion in consequence of a correspondence which he lately had with Dr. Lynch of Loughrea. That gentleman, about three weeks ago, when sending his annual subscription, sent also a donation of £5, and further advised that cards should be used, as in many other societies, to get in small donations; at the same time promising to be himself a collector if furnished with one. He (Dr. Benson) immediately answered, that such cards had been formerly used, but with very little success; however, that he would be very glad if Dr. Lynch would try the plan again; and he sent him one of the old cards. In two days after, Dr. Lynch returned the card, filled with the names of half-crown and five shilling subscribers, and asked for another card, which was sent, and in a few days more returned, also filled, together with £3 2s. 6d. Dr. Lynch then asked for other cards, and said that nobody had refused him a small sum. Now, he (Dr. Benson) would be happy to supply the friends of this institution with such cards, and would recommend their use in collecting small sums from *medical men*, where larger sums were not likely to be obtained.

Dr. CHURCHILL proposed the fifth resolution:—

That the society announces with pleasure the formation of another branch—namely, in Waterford—during the past year, and would earnestly recommend the formation of branches in Limerick, Galway, Derry, Sligo, Drogheda, Kilkenny, Clonmel, &c., believing that such associations materially forward the interests of the society, and prove very beneficial to the localities themselves.

He said that this society carried with it a double blessing: blessing those who give and those who receive. All agree that to relieve the fatherless and widow, and to minister to the wants of the distressed of our profession, is our duty, and the report shows that it has been done successfully, and surely the very exercise of benevolence, the combining together to do good, is calculated to draw closer the bonds of affectionate brotherhood between members of the same profession: the kindly feelings which are conjointly exercised towards those who are suffering are necessarily reflected towards those who are sharers with us in the good work.

Dr. PATERSON said he had great satisfaction in seconding

the resolution, and fully coincided in the remarks made on the subject both by Dr. Macdonnell and Dr. Churchill. The resolution passed unanimously.

Dr. BEATTY said, I rise with feelings of no ordinary kind to propose the resolution with which the committee have honoured me. The resolutions that have been hitherto agreed to at this meeting have been of a cheering character; they spoke of present prosperity and of hope for the future. But if we have reason to congratulate ourselves on the success of our undertaking, we should recollect that it is to the untiring energy of a few we are indebted for that success, and that the zeal of the few who originated and carried on the institution in its infancy is the main cause of the prosperous condition in which we now find it. To the secretaries and the late lamented treasurer is to be ascribed all that has been achieved for the relief of our distressed brethren, and the annual vote of thanks so regularly given to those officers is evidence of the estimation in which their services are held. It is with sincere sorrow I ask you to place on record a vote of a very different kind. Since we last met, since we last cordially united in a vote of thanks to our then treasurer, it has pleased the Almighty to remove him from amongst us. We have lost one of the great supports of our institution, one who took an early and lively interest in its formation and undertook the laborious and important office of treasurer at the very commencement of our struggle for existence. His doing so was of immense importance, for his high character for moral excellence gave a weight and respectability to the office, and inspired confidence, which was most essential to the success of the establishment. How he discharged his duties, the accuracy of his accounts fully testify, and the manner in which the claims of applicants were considered, and the unflinching honesty of purpose with which his opinion and advice were given upon the several cases that came before the committee will be long remembered by those who were so happy as to serve with him. It may be well said that his services were of incalculable benefit, and his loss will be a serious blow to the Medical Benevolent Fund. But it was not alone in his connexion with this society that our late lamented friend was to be esteemed. In all the relations of life, private as well as public, Maurice Collis was preëminently distinguished for those qualities that constitute the highest character to which man can aspire, the qualities that make the benevolent Christian gentleman. Without entering into any particulars of his self-devotion to the interests of the many institutions of which he was an active member, or of his unostentatious charity, I think I may safely say, that by all who knew him he was esteemed and loved. Many a widow's tear has fallen and will fall for his loss, and many an orphan will miss the well-timed assistance which his liberality so freely bestowed. I will not delay further, though the subject is a tempting one, and hours might be spent upon it, but I will conclude by reading the resolution to which I anticipate the hearty concurrence of the meeting:

That it is with deep and sincere regret the society has to record the death of its esteemed treasurer, Maurice Collis, Esq., whose faithful and efficient services conferred incalculable benefits on this institution.

Dr. COLVAN of Armagh, in seconding the resolution said, that after the very eloquent observations of Dr. Beatty regarding the decease of their late highly respected and deeply lamented friend and fellow-labourer in the cause of benevolence, Maurice Collis, Esq., who so long and so efficiently filled the office of treasurer to this society, it would be presumption in him to attempt to detain this meeting with any lengthened remarks; yet when he considered the very laborious position he (Mr. Collis) occupied, and the ease, affability, and correctness with which he carried on his very extended correspondence, his no less numerous accounts, knowing, as every one must who has anything to do with such office, the trouble and anxiety unavoidably attending them, he must say he was lost in admiration of his zeal and talent, and no less impressed with the very great loss this society has sustained. It was a matter he thought of the utmost consequence to

the stability of such institutions as this, that the subscribers and the public shall have the greatest confidence in the character and ability of the officials; the esteem and confidence of all had been long and worthily bestowed upon Surgeon Collis for his kindness, discrimination, and Christian benevolence. Perhaps he (Dr. Colvan) might be permitted here, as not quite out of place, to state his opinion of the gentleman, Dr. Duncan, who has so worthily and so correctly managed the office of treasurer since the loss of their friend, and on whom a considerable portion of his mantle seems to have fallen; he appears, indeed, a truly worthy successor to such a man, and he hoped the society and this meeting would be able to prevail on him to continue to hold the office of treasurer, and thereby be enabled to carry on the good work without interruption. He trusted they would, one and all, in their respective spheres, endeavour to render themselves useful in carrying on this labour of Christian love and duty, which is alike honourable to the profession and to the country.

The seventh resolution as follows, was spoken to by Dr. LEES and Dr. DENHAM, and passed unanimously:—

That the thanks of this society are eminently due to our honorary secretaries, Dr. Kingsley and Dr. Benson, for the unwearied zeal and success with which they continue to discharge the duties of their office.

Dr. CORRIGAN said he believed it would not be easy to find a more efficient committee nor any which would more perfectly command the respect and confidence of the profession than that which he was about to name. He begged, however, to except from this praise one gentleman with whom he happened to be most intimately acquainted. He confessed he was a very bad attendant at the committee meetings; but the person really to blame for his neglect of duty was their secretary. Yes, it was Dr. Benson who was really to be blamed for his (Dr. Corrigan's) absence from those meetings. He had such entire confidence in the zeal, the judgment, and the impartiality of that gentleman, that he felt he could not better promote the interests of the society, and the benevolent objects it had in view, than by leaving as much as possible to their secretary. In conclusion, he proposed the eighth resolution, which is as follows:—

That the following be the committee, treasurer, secretaries, and trustees, for the ensuing year:—T. E. Beatty, M.D., T. Brady, M.D., R. Collins, M.D., D. J. Corrigan, M.D., Sir P. Crampton, Bart., C. P. Croker, M.D., J. W. Cusack, M.D., J. F. Duncan, M.D., R. J. Graves, M.D., W. Hargrave, M.D., J. Harvey, M.D., E. Hutton, M.D., A. Jacob, M.D., E. Kennedy, M.D., G. A. Kennedy, M.D., T. G. Geoghegan, M.D., J. Macdonnell, M.D., Sir H. Marsh, Bart., J. Mollan, M.D., Wm. F. Montgomery, M.D., J. O'Beirne, M.D., R. Shekleton, M.D., W. Stokes, M.D., R. C. Williams, M.D., Dr. Colvan, Armagh, R. Stewart, M.D., Belfast; D. K. Lloyd, M.D., Cork, A. Erskine, M.D., Newry, W. Carroll, M.D., Waterford—Dr. Duncan, 19, Gardiner's-place, Treasurer—Wm. Kingsley, M.D., Roscrea, and C. Benson, M.D., York-street, Dublin, Honorary Secretaries—Trustees: Dr. Macdonnell, Dr. Mollan, and Dr. Duncan.

Dr. NUGENT (Inspector of Lunatic Asylums) seconded the resolution, and said he felt so thoroughly convinced of the value of this institution that he was determined to lose no opportunity of recommending it wherever he went, and that he would urge the formation of branches in every large town that he visited, and encourage them in the most effectual way he could—namely, by becoming himself a member of each.

Dr. MONTGOMERY was then requested to leave the chair, and Dr. ROE of Cavan, having been called thereto, the marked thanks of the meeting were given to Dr. MONTGOMERY for his dignified conduct in the chair.

**CHOLERA.**—The troops in possession of the Great Pagoda, Rangoon, which was taken after a fearful slaughter, are suffering frightfully from fever and cholera, in consequence of the stench created by the heaps of dead bodies that were left by the enemy. Captain Hunt, 80th Regiment, has fallen a victim to cholera; and another officer was in a hopeless state at the time the dispatches left, which stated that an awful mortality prevailed among the troops.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JUNE 16, 1852.

## UNIVERSITY REFORM—REPORT ON OXFORD.

In our number of the 2nd inst., we made our readers acquainted with the nature of the Report to which we now again have to direct their attention, and to which we shall probably have to address ourselves on other occasions. Derived as the title of Doctor of Medicine is from Universities, those who possess it should know what a University is, which we believe many of them do not; for even the members of some Universities are misinformed on the subject: indeed we do not ourselves pretend to a perfect knowledge of the conditions which come within the term, seeing the variety of constitutions to which it is applied. In Oxford and Cambridge, there seem to be true Universities with Colleges under their control; in Dublin, Trinity College is entitled a University, although it evidently has not the usual ingredients of university government; the Queen's University in Ireland and the London University have their Chancellors, Vice-Chancellors, and Senate; and in Edinburgh, the Town Council appears to exercise supreme power. Be this, however, as it may, we find the Commissioners expressing very free opinions as to the exercise of the powers vested in the academic authorities at Oxford, and amongst other things very unceremoniously questioning the expediency or policy of manufacturing Medical Doctors, or indeed dabbling at all in special professional education. To those who, from ignorance of the true nature and original object of these institutions, have all this time been considering them establishments for instruction with a view to the practical application of knowledge, it will doubtless appear strange that their use in this way should be questioned, but their wonder will cease when they find such expression of dissent from the opinion by the Commissioners before us. We extract a few paragraphs from the Report:—

"We have no desire that professional education, in the strict sense of the word, should be given in Oxford." (p. 71.)

"It is not recommended that the university should be made a place of professional education, at least not for law and medicine." (p. 72.)

"It is not thought that a complete school of medicine could or ought to be established in Oxford." (p. 80.)

"We must here repeat, what we have more than once said before, that we cannot consider it desirable to establish in Oxford a strictly professional education." (p. 77.)

"We have come to the conclusion, that, so far at least as regards the degrees in theology, law, and medicine, it will be difficult to make them anything more than titles which designate the academical standing of those who obtain them." (p. 85.)

In the evidence of H. H. VAUGHAN, A.M., the same view is expressed:—

"There is much in medical and in legal studies which cannot be effectually taught in the university; so also of engineering, agriculture, politics."

The advocates, however, for the perversion of Universities to the purpose of providing certificates of proficiency in practical acquirements, however applicable to Oxford and Cambridge, are not so to Universities in metropolitan cities, where all the necessary means of practical education are at hand; but it is here especially that the duties of the institutions for preliminary education should be defined

and restricted so as to make them ancillary to professional education. On this point the Commissioners seem to agree with all persons who have considered the subject, except those who derive income from practices suggested by a different view. They evidently contemplate a coöperation between the Universities and the institutions for professional education, instead of the unseemly competition with them, which prevails in some cases for the purpose of eking out the inadequate stipends of superfluous professors. With respect to this, they observe in reference to preliminary or elementary instruction:—

"There is one practical use to which the school of physical science may be turned, so important as to claim especial notice. We are led to believe that, by means of this school, the university might be brought into alliance with the higher branches of the medical profession, in the same way that, by the school of jurisprudence, it might be associated with the profession of the law." (p. 80.)

And again, holding the same object in view, they add:—

"If the university were to give such lectures and such examinations as would satisfy the Colleges of Physicians and Surgeons, these learned bodies might perhaps be induced still further to coöperate with the university." (p. 82.)

Instead of this, however, we find some of these institutions abandoning their legitimate duties and assuming those which from their very nature they are utterly incapable of discharging. While the most reprehensible contrivances are resorted to for the purpose of facilitating the introduction of uneducated persons into our profession by a sham matriculation, the most stringent regulations are adopted to enforce attendance on the Lectures of the Medical Professors; thus converting the University into a school for the benefit of those who really do not form part of the institution at all. With respect to preliminary education for Medical Students, we have latterly heard a great deal, but we find that deficient as Dublin University is in this respect, Oxford is not much better, for here is what the Commissioners have to say respecting it:—

"The university is blameable for the little encouragement which, even considering all it has done by its recent improvements, it has yet given to those physical sciences which medical students ought to learn before they begin their strictly professional course." (p. 71.)

In fact, to the Universities our profession is very little indebted, indeed, for the general education of its members, however the recipients of academic honours may fondly flatter themselves to the contrary. Our brethren having sons now in Trinity College will find presently that the value received for their heavy disbursements is greatly disproportioned to the outlay; but the ARCHBISHOP OF DUBLIN, in his own peculiar way, handles this better than we can. Illustrating the merely titular character of the higher degrees, he says of examinations:—

"After a few terms, the whole will become an empty form; the exercises will be understood to be a mere form. I alluded to the story in the *Spectator* of the Indian, Maraton, who went to the Land of Shadows—the Indian Elysium—to visit his deceased wife, Yaratilda. He found it surrounded (instead of the river Styx) by a seemingly impenetrable thicket of thorn bushes, and for a time was at a loss; but he soon found that it was only the ghost of a departed thicket, the shadows of thorn bushes, and he walked through it without any difficulty. Even so, I said, this examination will have some effect till it is discovered—as it soon will be—that it is only a shadow. And thus it proved on the experiment being tried." (Evidence, p. 25.)

"At Trinity College, Dublin, there is not even any pretence of domestic control over those students who lodge in the town; their own friends are to see to that, as in the case of day boys at a school." (Archbishop Whately, p. 26.)

## PHARMACY REFORM.

TREATING of University Reform and Pharmacy Reform at the same time reminds us of the truth of the saying, that "there is but one step from the sublime to the ridiculous:" not, indeed, that we mean to insinuate that there is much sublimity in the one case, or much that is ridiculous in the other, except by contrast; but there is evidently a close relationship between diploma and pill-box, and so by the chapter of accidents we find ourselves handling both together. Of the two, however, we almost lean to the Pharmacy Reform, believing that our patients will suffer less from bog Latin than bad Drugs. This Pharmacy Bill improves as it "progresses," and all that we have to regret respecting it is the probability of its not passing, in consequence of the delirium which precedes parliamentary dissolution. We observe that a suggestion has been made to introduce a stringent and unequivocal clause to forbid the practice of medicine by Chemists, which we hope may be adopted. We know that such a clause may not effect its object completely, but it may partially:—

Whatever may be the fate of the Pharmacy Bill now before parliament, some progress has been made during the present session. Evidence has been taken by a select committee of the House of Commons respecting the state of pharmacy in Great Britain and in other countries, the exertions of the Pharmaceutical Society for the removal of existing abuses, and the plan proposed for that purpose, with the opinions of various authorities on the subject. This evidence is placed on record; and if the early dissolution of parliament, or any other circumstance, should prevent the passing of the bill during the present session, the recorded facts will be available on the reassembling of parliament. The evidence above referred to places the society in possession of information as to the grounds upon which the bill has been opposed, and the arguments adduced in support of the same. The only objections worthy of notice are, first, the impression that the bill will create a monopoly, and deprive the public of the convenience of purchasing common medicines of grocers and general dealers, in small villages or other neighbourhoods where there is no regular chemist and druggist; and secondly, the fear entertained by some medical practitioners that the chemists are following in the footsteps of the old apothecaries, and endeavouring to become medical men. The council believe both these objections to be altogether imaginary. The bill does not propose to interfere with the sale of common medicines by grocers and others, provided such persons do not pretend to be pharmaceutical chemists. The prohibition is not against the exceptional cases in which the necessities of the public may require that medicines should be obtainable from such persons, but it is against the fraudulent assumption of a pretended qualification. On the other hand, the entire medical profession being exempted from all interference, the bill confers no monopoly in that direction. The council are aware that some members of the society have considered the bill not sufficiently stringent in its provisions for the protection of pharmaceutical chemists, but it would have been impossible to carry out all that was desired in this respect, and the policy of the concession is demonstrated by the fact that the doubt whether this concession is sufficiently explicit has been a source of objection. In the opinion of the council, the bill will have an important influence in raising the character and position of the pharmaceutical chemists, although it will not effect all that some parties desire. The second objection above stated, is founded on the belief that the improved status and position will tend to convert chemists into medical practitioners, and those who entertain this opinion desire the introduction of a clause prohibiting chemists, under a heavy penalty, from prescribing either in their own shops or elsewhere. It would be inconsistent to enforce this provision against chemists for the protection of medical practitioners, and to deny to chemists a similar protection against unqualified vendors of medicines. The same principle is applicable to both cases, and the Pharmacy Bill avoids this inconsistency by granting on one side all that is claimed on the other. The council believe that the direct tendency of the bill will be the reverse of that which has been above stated, that it will tend to promote a better understanding between medical men and chemists with regard to their respective functions, and will ultimately lead to the separation of pharmacy from medical practice, by mutual

arrangement, to an extent which could never be carried out by party contentions and obnoxious penalties. It must be remembered, that whatever encroachment may be made by chemists on the province of the medical practitioner, the encroachment is mutual; and that so long as medical men keep shops and carry on trade as chemists, they are provoking retaliation, and fostering a kind of competition injurious to both parties and to the public. This evil is aggravated by the circumstance that the chemists, having no recognized status in their own province, are not restrained by the moral influence of professional ethics, but each individual acts according to his own caprice, and those who transgress beyond due bounds bring discredit on the entire body. The Pharmaceutical Society has always resisted the introduction of the system of persecution which has been attempted by some of the advocates of medical reform, but has, at the same time, carefully abstained from any assumption of medical functions, and has endeavoured to promote a reform of abuses by means of improved education, and the recognition of pharmacy as a distinct professional pursuit.—*Phar. Jour.*

## GLASGOW UNIVERSITY.

To the Chair of Practical Medicine, recently become vacant by the death of Dr. William Thomson, Mr. Secretary Walpole has nominated Dr. John Macfarlane. The candidates were very numerous, including, from the University, Rainy, Professor of Forensic Medicine; Pagan, Professor of Midwifery; and Mackenzie, Lecturer on the Eye. From Anderson's Institution, Anderson, Professor of Practical Medicine; and Watson, Professor of Physiology. From Edinburgh, Douglas, Lecturer on Clinical Medicine; Wood, author of "Homeopathy Unmasked," and Gairdner, Pathologist to the Royal Infirmary. None of these gentlemen could have much chance with the successful candidate, as he commanded great political influence. The annual emoluments, £600 or £700.

We give this news as we find it, not sympathising much with those who attribute the result to political interest. Be such appointments good or bad, they may, we believe, be as safely entrusted to a SECRETARY OF STATE as to the patronage of any University authorities.

M. W. HANLON, M.B.

Now ready, post 8vo, price 9s. 6d., sent free by post,  
**A PRACTICAL TREATISE ON DISEASES OF THE SKIN.**

By J. MOORE NELIGAN, M.D., M.R.I.A.

Dublin: J. Fannin and Co. London: Longman and Co. Edinburgh: MacLachlan and Stewart.

Now ready, 8vo, of 510 pages, bound in roan, price 6s. 6d.,  
**THE PRESCRIBER'S COMPLETE HANDBOOK:**  
 Comprising the Principles of the Art of Prescribing, a Materia Medica containing all the principal Medicine employed, classified according to their natural families; with their Properties, Preparations, and Uses, and a Concise Sketch of Toxicology.

By TROUSSEAU and REVEIL.

Edited, with Notes, by J. BIRKBECK NEVINS, M.D.

LECTURES on HISTOLOGY, delivered at the Royal College of Surgeons, England. By JOHN QUEKETT, Author of "A Practical Treatise on the Microscope." 8vo, with 159 Woodcuts, 10s. 6d.

London: H. Baillière, Publisher, 219, Regent-street, and 290, Broadway, New York.

**THE ROYAL MEDICAL HALL,**  
 64, DAME-STREET, DUBLIN.

 *Change of Proprietorship.*

**BEWLEY, OWEN, AND CO., APOTHECARIES,**

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

**THE ROYAL MEDICAL HALL,**

beg particularly to state, that henceforth

**THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS**

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

**BEWLEY, OWEN, AND CO.'S ESTABLISHMENT** embraces the SALE of EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

\* \* GENUINE COD-LIVER OIL,  
 of the finest description.

*The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.*

#### **WATERFORD UNION.**

THE Guardians of the above Union will, on Thursday, the 24th inst., proceed to the appointment of a duly qualified

#### **APOTHECARY**

for the Workhouse and Fever Hospital of the Union, at a salary of £100 per annum, with apartments, coals, &c. &c.

In addition to his medical duties, the Apothecary will have to keep the Registry, Dietary, and other Books of the Hospital; to take the general superintendence of that institution as Resident Medical Officer; to superintend the proper appropriation of the Stores, &c.; and enforce the regular discharge of the duties of all the subordinate Officers.

The Guardians have pledged themselves not to give any promise that may prevent them from Electing only the Candidate having the highest testimonials for moral character, professional qualification, and experience.

Proposals, accompanied by testimonials of competency, &c. &c., will be received by me up to twelve o'clock on Wednesday, the 23rd inst., in order that they may be examined by the Fever Hospital Committee, who will meet for that purpose.

It is expected that all Candidates will be in attendance on the day of Election, if not before the Committee on the previous day.

By order of the Board,

RICHARD BURKE, Clerk of Union.

Clerk's Office, June 12, 1852.

#### **TO PHYSICIANS, SURGEONS, AND DRUGGISTS.**

**BROWN'S CANTHARIDINE BLISTERING TISSUE,**  
 PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

#### **BROWN'S TISSUE DRESSING,**

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

*Extracts and Editorial Note from the New York Journal of Medicine.*

"March 1, 1850.

"**BROWN'S CANTHARIDINE TISSUE.**—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

*From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.*

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,

"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,

"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

*Superior Dissecting Instruments well worth the inspection of the Student.*

#### **THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention*; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

# DUBLIN AGENCY.

\*R. Partridge, Esq., F.R.S., King's College Hospital.  
\*R. Quain, Esq., F.R.S., University College Hospital.  
Robert Smith, Esq., Endsleigh-street.  
F. T. White, Esq., Lincoln's Inn.  
J. H. Whiteway, Esq., Lincoln's Inn Fields.

Those marked with an asterisk being Medical Examiners to the Society.

*Auditors*—John Brown, Esq., Surgeon, Hammersmith; George Carew, Esq., Lincoln's Inn Fields;  
F. W. Remnant, Esq., Lincoln's Inn Fields; and E. Ray, Esq., Surgeon, Dulwich.

*Bankers*—Messrs. Praed, Fane, and Co., Fleet-street. *Standing-Counsel*—Thomas Webb Greene, Esq.

*Solicitors*—Messrs. Pooley, Beisley, and Read, Lincoln's Inn Fields.

*Secretary*—Frederick James Bigg, Esq., 126, Strand, London.

This is the only Society in connexion with either the Medical or Legal Profession, founded on the principle of **MUTUAL ASSURANCE**.

This principle is the most beneficial to the Assured, amongst whom **THE WHOLE NET PROFITS ARE DIVISIBLE**.  
The Society has a Subscription Capital to guarantee the prompt settlement of claims.

The business of the Society includes—

**ASSURANCES**, on a Single Life, with or without profits; also on Joint Lives, and on Survivorships.

**ANNUITIES**, for Lives and Limited Terms, Immediate, and on Survivorship.

**DEFERRED ANNUITIES**, with the privilege to the Grantees of receiving, in lieu thereof, either their present value in money, or a policy for the equivalent sum at death.

**ENDOWMENTS** for Widows and Children.

The Society also offers new and distinctive forms of Assurance; as—

**ANNUITIES TO CHILDREN**, payable from the death of a parent or other person, or for a stated number of years, commencing at a given age.

**ENDOWMENTS** at all ages.

**AND ALL OTHER** sound and practicable **PROVISIONS** contingent on human life, or for terms certain.

**INVALID** Lives Assured at equitable rates.

### ADVANTAGES OFFERED BY THE SOCIETY.

**THE RATES OF PREMIUM**, which are founded on the most accurate observations of the duration of human life, are as moderate as is consistent with due Security.

**PREMIUMS** may be paid either Yearly, Half-yearly, or Quarterly, or in a single payment, or in a limited number of payments, or by an increasing or decreasing scale; or half the Premiums may remain unpaid at simple interest for the first Seven Years, and may be then paid off, or remain as a Debt upon the Policy, at the option of the Assured.

**MILITARY AND NAVAL OFFICERS** Assured at the ordinary Rates, until called into actual service.

**THE AGE** of the Life Assured will at any time be admitted on satisfactory evidence being produced.

**CLAIMS ON POLICIES** will be paid within Three Months after satisfactory proof of Death shall have been produced.

**NO ENTRANCE OR ADMISSION FEE**, or other Charge beyond the Stamp of the Policy, which may be commuted by a small Annual Payment.

**ANY MEMBER** wishing to dispose of his Policy, the Directors will purchase it for a sum of Money, payable immediately or at his death; in which latter case the value will be secured by the grant of a New Policy, without further payment, to rank in date as a continuation of the Old Assurance in the future division of Profits.

### PREMIUMS FOR ASSURING £100 AT DEATH.

WHOLE TERM OF LIFE.						
With Profits.			Without Profits.			
Age	Annual Premium.	Single Premium.	Annual Premium.	Single Premium.	Seven Years.	One Year.
15	£1 10 10	£33 6 10	£1 7 10	£30 0 3	£0 16 9	£0 16 0
30	2 6 2	44 2 9	2 1 7	39 14 7	1 5 8	1 3 2

And so on in proportion up to age 70.

Prospectuses, Forms of Proposal, and every further information, will readily be supplied on application, either personally or by letter, to the Actuary, or to any of the Society's Agents.

### MEDICAL REFEREES.

### THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. FREKE, A.B., M.B., M.R.I.A.

(Continued from page 247.)

(*The Specific Physiological Function of Nerves generally.*)

In my last communication, I made an attempt, in a general way, to place concisely and clearly before the reader—1st, certain of what to me appear to be among the more important topics of consideration—in relation to organic or living creation—to which I have hitherto made an effort to direct his attention, and that for the following purpose—namely, in order to be thereby enabled the more clearly and concisely to lay before him; 2ndly, certain of what to me appear to be among the more important topics of consideration—in relation to organic or living creation—which, as I regard it, now demand investigation. Such, I say, was the design of my last communication, the leading points of which I shall for perspicuity here rapidly recapitulate, and having done so shall proceed to their application.

The special objects of consideration at present before us are those organic tissues or organized structures which have received their organization (or in other words, which have been *generated*) for the purpose of giving development to what are termed "*phenomena of animal life*;" the terms "*animal life*" being employed, as the reader is aware, in contradistinction to what is termed vegetative or *organic* life. In other words, the organized structures into whose physiological function we have now to inquire, are the several component constituents of the animal frame which have been respectively named nervous tissue, vascular structure, muscular fibre, and cerebral matter.

To *such* organized structures (namely, as are at present before us), in contradistinction to another class of organized structures, entirely distinct in their nature, and designed to develop another and an altogether distinct class of physiological phenomena (that is, in contradistinction to those organized structures whose function is to *confer* or *impart* organization: in a word, in contradistinction to such organ-

ized structures as those whose function was to *generate* structure): to such organized structures, I say, as are at present before us (in contradistinction to that other class referred to) I have, as the reader is already aware, applied the terms "*organized residual product*." I have done so (among other reasons with which the reader is already familiar) with the following motive—namely, with a hope that by the adoption of some such form of phraseology which involves in it nothing whatever of hypothesis, the reader might thereby be enabled, with facility and clearness, accurately to discriminate between the nature and function of such organized structures (namely, what I have termed *organizing agents*) as develop what are termed "*phenomena of organic life*;" and the nature and function of the organized structures (namely, *residual products*) at present before us which develop another and an altogether distinct class of physiological phenomena, named "*phenomena of animal life*."

Into the nature of the function of the former of these two classes of organized structure (namely, of the *organizing agents* which develop "*the phenomena of organic life*"), as also into the nature of the requirements which it has been made essential should be fulfilled so as to admit of that function's being discharged in a normal or natural manner, I have already endeavoured to inquire; consequently, our present inquiries have relation to the latter of those two classes of structure (namely, to the organized residual products which develop the phenomena of *animal life*), and the investigations about to be engaged in with regard to those products are of the following twofold description—namely, 1st, as to the nature of the function of each of those residual products individually; and 2nd, as to the nature of the requirements which it has been made essential should be fulfilled, so as to admit of that function's being discharged in a normal or natural manner. Such are, I say (as it strikes me) the two questions of leading importance which remain for us still to investigate.

To the organized residual products at present before us (namely, such as develop phenomena of *animal life*) I have, as the reader is further aware, in contradistinction to an-

other species of organized residual products, entirely distinct in the nature of their relations, and designed to perform another and an altogether distinct species of physiological function (in contradistinction, for example, to such organized residual products as the albumen and the fibrin employed in the generation of the residual products before us); to the organized residual products, I say, which develop the phenomena of *animal* life, I have further (in contradistinction to that other species of product referred to) applied the terms "final or ultimate results" (viz., products) of the regenerative process. I have been induced to make use of such terms with the hope that by the adoption of an expression which involves in it no hypothesis or theory, I might thereby enable the reader, with greater facility and clearness, accurately to recognize the nature of the relation (and consequently to discriminate between the distinction in function) which the organized residual products, such as nerves, muscles, &c., which develop "phenomena of *animal* life," bear towards those organized residual products, such as albumen, fibrin, &c., which are concerned merely in the generation of such products as the former. In a word, with the hope that he might thereby be enabled, with greater facility and clearness, accurately to discriminate between the nature of an organized residual product, whose specific physiological function is to stand in the relation of what has been termed "nutriment" to an organizing agent, and such organized residual products as have a specific physiological function of a very different nature to perform—namely, the development of the "phenomena of *animal* life." Into the questions of leading importance (namely, 1st, as to the process of generating; and 2nd, as to the nature of the physiological function), into the questions, I say, of leading importance with regard to the *former* of these two species of organized residual product, I have already endeavoured to inquire; consequently it is the latter of these two distinct species of residual product (namely, the *final* products or results of generation) to which I would now desire to solicit the reader's attention, and the investigations I am desirous of attempting with regard to those final results have relation to the functions they are respectively called upon to fulfil. I employ the term *function* in contradistinction to *construction*—that is, in contradistinction to the process of constructing or of generating those final results (which is, in other words, in contradistinction to the development of the phenomena of *organic* life), and that inasmuch as the latter (namely, the construction or generation of those final results, or which is the same thing, the development of the phenomena of *organic* life) has already engaged our attention. In other words, having already attempted to investigate both the process and the agency whereby the final results of the regenerative process have been constructed out of inorganic or mineral matter (during the progress of which construction we saw development given to the phenomena of *organic* life), the questions which remain for investigation with regard to those final results have relation to the functions for the discharge of which their construction has taken place (and during the progress of the discharge of which functions we shall see development given to "the phenomena of *animal* life").

With one fact in relation to the function of the several residual products before us, the reader is already familiar—namely, he is aware (from an analysis of urine, &c., before and after that function has been discharged), he is, I say, aware that in connexion with the discharge of its physiological function, each of those residual products undergoes what I have termed the process of *degeneration*—that is, undergoes such change or alteration in its own constitution as that which had hitherto constituted one of the component constituents of man becomes effete, and eventually (as a result of the discharge of its function) requires to be eliminated as of no further use in the system. He is aware that in connexion with the discharge of its physiological function each of those final results of the process of organization (viz., generation) undergoes the process of *disorganization*, whereby that which had hitherto existed in an highly organized condition is eventually reduced (as a re-

sult of the discharge of its function) to the condition of inorganic or mineral matter. He is aware, for example, that in connexion with the discharge of its physiological function, that highly organized structure named muscular fibre undergoes such change or alteration in its own constitution as to be eventually reduced (as a result of the discharge of its function) to the unorganized condition of carbonate of ammonia and water.\*

With such fact, I say (in relation to the function of those structures), the reader is already familiar. But there are two additional facts in relation to that function into which we have still to inquire—namely, we have to ascertain, 1st, what is the physiological function which each of the residual products referred to is specifically called upon to discharge? and 2nd, what is the *provision* which has been made for *effecting* the discharge of that function? The two questions, in other words, which I would now desire to propose for investigation are the following—viz., 1st, what is the specific function which Nature has specially assigned to each of those components of the animal frame which have been respectively named nervous tissue, vascular structure, muscular fibre, and cerebral matter? For the fulfilment of what specific physiological function has provision been made for the generation of *each* of those residual products individually? *Why*, or for the accomplishment of what special design, does each of those organized tissues exist? and 2nd, what is the special arrangement which has been adopted by Nature whereby each of those residual products individually shall be *caused* to discharge that specific physiological function at such time and with such degree of activity or intensity as may be required in the discharge of that function? Such are, I say, as it strikes me, the two questions of leading importance which suggest themselves for investigation in relation to the function of the residual products before us.

The latter of these two questions—namely, as to the

\* The reader will have the goodness to observe that these materials (viz., carbonate of ammonia and water) are exactly the very species of inorganic or mineral matter upon which (as I pointed out in one of my early communications) the simplest or lowest species of organizing agent has been adapted by Nature for *conferring organization*. These *inorganic* materials (namely, carbonate of ammonia and water) we saw converted by the lowest or simplest species of organizing agent into an *organized* residual product, possessed of but the lowest or simplest degree of organization. This organized residual product (namely, possessed of but the lowest or simplest degree of organization) we subsequently saw pushed progressively forward by gradually ascending organizing agents till (having passed through the conditions respectively of albumen and of fibrin) we at length beheld those materials which we had first seen in the unorganized condition of carbonate of ammonia and water; converted, by successive repetitions of the process of generation, into that highly organized structure to which we give the name muscular fibre. (During the entire passage of those materials from the unorganized condition to the condition of muscular fibre, &c., we saw development given to the phenomena of *organic* life.) That muscular fibre we now see (by an *opposite* process to that of its *generation*, and consequently by the process of *de-generation*—by an *opposite* process to that of its organization, and consequently by the process of *disorganization*), that muscular fibre, I say, we now see, as a result of the discharge of its function, reconverted into carbonate of ammonia and water; that is, again reduced (as a result of the discharge of its function) to that condition in which alone its components have been adapted by Nature for standing in the relation of what is termed "nutriment" to the lowest or simplest species of organizing agent. (During the process of this degeneration we shall see development given to the phenomena of *animal* life.) By this lowest or simplest species of organizing agent, these inorganic materials are a second time organized; they are again pushed progressively forward to the condition of muscular fibre, &c.; and again, during that progressive *ascent*, are developed the phenomena of *organic* life. They, then, a second time, undergo the process of *de-generation*; and again, during their *de-scent*, are developed the phenomena of *animal* life. Such is the nature of the circle of changes which is in perpetual rotation to constitute *all* to which we give the name "life."

provision or arrangement adopted by Nature for causing the discharge of that function (or in other words, for causing what I have termed the degeneration and eventual disorganization of the organized structures in question), the latter of these two questions, I say, engaged our attention to a partial extent in my last communication, and in relation thereto I endeavoured to direct the reader's attention to the following fact—namely, that the cause of the degeneration and ultimate disorganization of each of the organized structures referred to may be said to comprise under it *two distinct elements*—that is, that each of those organized structures which develop what have been termed “phenomena of animal life,” and which, during the development of such phenomena, undergo a process (namely, what I have termed the process of degeneration) which eventuates in the complete disorganization of that hitherto organized structure; that each, I say, of those organized structures (in order that it may undergo the process referred to in a normal or natural manner) requires the presence and operation of the following two distinct causes of its degeneration and ultimate reduction to the condition of inorganic or mineral matter—namely, 1st, what I have termed a *specific stimulus*; and 2nd, what I have termed an *incidental stimulus*. The joint operation of these two distinct species of what I have termed *stimuli*, appears to me to have been made requisite or essential to the *normal* development of the function of those structures.

By the latter of these two expressions—namely, by the terms “incidental stimulus,” I desire (as I have already endeavoured to convey to the reader) to express, in other words, this—namely, some *chemical* agent through whose instrumentality the *chemical* force which already exists in the elementary components of that organized structure (but mark distinctly, exists in those components without producing therein its normal or ordinary *chemical* effects), some chemical agency, I say, through whose instrumentality the chemical force existing in those components may be so called into operative action, or if the term be allowed, so *augmented*, as to be enabled (when that organized structure has been so acted upon—by some specific cause to be presently referred to—as to admit of such result taking place), as, I say, to be enabled to produce in those components the ordinary or normal effects of *chemical* force.\*

\* Lest there might possibly be any of my readers to whom, from a want of familiarity with such forms of expression, the terms “chemical force” may not convey any very definite meaning, I shall, in order to be clearly intelligible to such, endeavour to explain somewhat more distinctly what it is desired should be conveyed by those terms. By the expression “chemical force,” as applied, for instance, to carbon and to oxygen, nothing more or less is meant to be expressed than simply this—namely, *that* (whatever it may happen to be, and upon this subject no opinion whatever is expressed), *that*, I say, whatever it be, which *forces* carbon and oxygen (when unrestrained by some opposing cause) into that species of combination or union to which has been given the name “chemical compound;” into that form of combination, for example, which has received the name “carbonic acid.” As applied to nitrogen and hydrogen (and to all mineral elements universally) the same is the meaning—namely, simply that (whatever it be) which causes nitrogen and hydrogen to enter into *chemical* combination; into such combination, for example, as that in which they exist in what we call “ammonia.” And as applied to carbonic acid and to ammonia (and to all chemical compounds universally), the same is exactly the meaning—namely, *that*, whatever it may happen to be, which *forces* these two compounds (when unrestrained by some opposing cause) into that form of union which has received the name “carbonate of ammonia.” That such forms of union *do* take place between the elements referred to, when unrestrained, the reader is aware. That *something* must have caused that union is obvious; and it is that something (whatever it may happen to be) to which is given the name “chemical force.” When I state that chemical force must of *necessity* exist in mineral matter, and that it is inseparable therefrom, I mean by such terms simply to express this—namely, that the tendency on the part of oxygen to unite (when unrestrained by some opposing cause) in chemical combination with carbon, *essentially* belongs to that element, and cannot be dissociated therefrom. In other words,

Some chemical agency by whose instrumentality the chemical force existing in the components of that structure may be so called into operative action or augmented as to be enabled to force those components (in opposition to their organized condition) under the complete control of their chemical laws, whereby those components eventually become reduced from the condition of an *organized* structure to that of a *chemical* compound. Let me not be misunderstood. When I state that the presence and operation of what I have termed an incidental stimulus appear to me to have been made essential to the normal discharge of the function of the structures before us, I mean by such terms to express this—namely, that (in addition to the operation of some specific cause to be presently referred to) it appears to me that Nature has made the normal discharge of the physiological function of the several organized structures before us dependent upon the presence and operation of the following *chemical* cause of its disturbance and functional action—namely, some agency through whose instrumentality or means may be called into normal operation, or (if such term be permitted) may be augmented, that chemical force which must of necessity exist in the chemical (viz., mineral) elements of which that organized structure is composed. I say must of necessity exist in those elements, inasmuch as chemical force is inseparably associated with mineral matter. Some agency through whose instrumentality or means such chemical force may be compelled (in opposition to the cause, whatever it be, of the *organized* condition of that structure) to produce the *normal* effects of chemical force (that is, cause a union in the form of *chemical* and not of *organic* compounds), by whose means, I say, such chemical force may be compelled to produce the normal effects of chemical force in those inorganic, inanimate, or mineral elements which we have already seen compelled (by an organizing agent, and in direct opposition to that chemical force) to assume the condition of an *organized* structure; or in other words, which we have seen forced by such agent, in opposition to their chemical force, to leave the inorganic or *chemical* condition of carbonate of ammonia and water, and assume the condition of an organized residual product. In a word, some agency or operative cause by whose instrumentality or means the chemical force inseparable from the mineral elements of

an element in which there existed *no* tendency to enter into chemical combination with carbon (when free and uncontrolled) would not be what chemists call oxygen. We cannot, then, dissociate the idea of chemical force from the idea we attach to the term “oxygen.” The same is obviously also the case with regard to other mineral elements, such, for example, as carbon, nitrogen, and hydrogen.

Now, the reader is aware, that in muscular fibre the four elements just referred to (namely, carbon, oxygen, hydrogen, and nitrogen), exist in combination; but he is further aware that those elements *do not* exist in that muscular fibre in *chemical* combination, or in the form of carbonate of ammonia, although chemical force is inseparable from those elements. Hence it is obvious that the chemical force in the elements of muscular fibre is restrained by some opposing cause (whatever it may happen to be) from forcing those elements into *chemical* combination.

There are none of my readers who are not aware of the fact, that meat cooked in Great Britain is frequently sent out in hermetically sealed cases to the East Indies, and to other remote countries; they are aware that even in a tropical climate such meat will resist decomposition for any indefinitely prolonged period, provided the access thereto of atmospheric oxygen be carefully excluded; and they are further aware that if the atmosphere be allowed to have access to that meat, the result is that it does undergo decomposition. Why is this latter fact so? It is for this reason—namely, that the oxygen of the atmosphere so augments or calls into operative action the chemical force existing in the elements of that meat, as that that force thereby obtains the mastery over the cause (whatever it be) which hitherto resisted its action; and now augmented or called into action by oxygen gas, that chemical force *forces* those elements to unite in the form of what are termed chemical compounds. The effect here produced upon that meat by the action of oxygen, appears to me to be the same as that produced by the same oxygen upon the muscular fibre, &c., of man, when so circumstanced as to admit of such result taking place.

which that organized structure (in direct opposition to that force) has been, if I might so term it, *built up*; by whose instrumentality, I say, or means such chemical force may be so called into operative action, or if the term be allowed, so augmented, as that the mineral element thus built up in opposition to that force may, as the result of such augmentation or action, be, if I might so term it, *pulled down*, and consequently that those mineral elements which had hitherto existed in the condition of what we term an *organized* compound may (as a result of the augmentation or action of that chemical force) be compelled to assume the opposite or *unorganized* condition to which has been given the name *chemical* compound. Such is what I would desire to convey by the terms "incidental stimulus."

The reader will now have the goodness to reflect for a moment on the three following facts, the truth of which no one will question—viz.:

1st. A chemical agent possessed of the properties here referred to *has been* supplied by Nature in the oxygen of the atmosphere which surrounds us.

2nd. The action of that oxygen upon organized structures *has been* made essential to the development of vital phenomena.

3rd. The component constituents of the organized structures which develop those vital phenomena *are found* (when the function of such structures has been completed) in combination with the oxygen of the atmosphere.

Hence to me it would appear to be obvious that the action here attributed to oxygen gas belongs or appertains (to say the least) to its *physiological* function. I say "belongs or appertains" to that function, meaning thereby to express this—namely, that whatever additional functions, whether imaginary or real, may be attributed to that chemical agent, in its relation to the development of vital phenomena, the disorganizing action attributed to it here must, as it appears to me, form of necessity (to say the least) an important portion of its physiological function.\*

\* A *secondary* function, if I might so term it, concomitant with the development of vital phenomena, must be the development of temperature. For during the disorganization of an organized structure (such as muscular fibre, &c.), by the combination of its components with oxygen gas, extrication must be given to caloric; and that to an extent bearing a constant proportion to the degree of activity or energy with which the process of disorganization takes place. For every condensation of oxygen (which takes place during its chemical combination) must of necessity be accompanied, to a proportional extent, with an extrication of caloric. Hence an augmentation of temperature during the development of vital phenomena; hence the reader can understand *why*, if cold, he runs to make himself warm. I would beg of the reader to reflect for a moment himself upon the *nature* of the action of oxygen gas.

He is aware of the energetic chemical properties of that agent; he is aware that the action of that chemical agent is essential to the manifestation of vital phenomena. Has he ever asked himself *why*? He is aware that he has himself been furnished with what is termed "a respiratory apparatus," and that the continuance of the respiratory process is absolutely essential during the continuance of the development of vital phenomena. Has he ever inquired what is the *necessity* for the provision of a respiratory apparatus? and *why* it is that the process of respiration must be constant? Has he, in a word, ever asked himself *what* is the action of oxygen during the manifestation of vital phenomena, and wherefore is it that such action is essential? Should he have never reflected upon so important a question, I would beg of him, while considering it, to bear in mind the three following facts—namely:

1st. The elementary constituents of which muscular fibre, &c., is composed, exist *before* that muscular fibre commences the discharge of its function in the condition of an *highly organized* structure.

2nd. *During* the discharge of the function of that muscular fibre, &c., the action of oxygen gas is indispensable.

3rd. When the function of that muscular fibre has been *completely* discharged, its elements exist in combination with oxygen gas, and in what I have termed a degenerated condition.

In connexion with these three facts, I would beg of him to reflect upon the following considerations—namely, if, from

If, then, in its physiological relations (that is, in its relation to the development of vital phenomena) such be in reality the function of that active chemical agent by which we have been surrounded, and upon the operation of which *in some way* every one is aware the development of vital phenomena *has been made in some way* dependent; if, I say, such be in reality its function, we may for perspicuity term that chemical agent (namely, oxygen gas) the *incidental stimulus* of an organized structure to the discharge of its physiological function—namely, to the development of vital phenomena. I employ the term *incidental stimulus*, as I have already acquainted the reader, in contradistinction to the term *specific stimulus*, and that for the following reason—namely, the *same* chemical agent (viz., oxygen gas) has been (as it were *incidentally*) the element selected by Nature to stand in exactly the same physiological relation to *all* such organized structures in existence (viz., organizing agents as well as residual products), to *all* such organized structures, I say, as are called upon to give development to vital phenomena: each and all require the presence and operation of *one* and the *same* chemical agent—viz., oxygen gas. Each distinct species of *simple* organizing agent (namely, each distinct link in the chain of progressively ascending organizing *atoms*), each and all, I say, require the presence and operation of the *same* chemical agent to enable them to develop (in a normal or natural manner) the phenomena of organic life. The same is the case also with regard to residual products. Each organized residual product which develops a phenomenon of animal life: each and all, I say, require the presence and operation of the *very same* chemical agent—namely, oxygen gas, to enable them (in a normal or natural manner) to develop their physiological functions. But such we have seen is not *all* that is required by those organized structures for the normal development of their functions. Each and every structure throughout organic creation whose function is to develop a vital phenomenon (including both organizing agents and residual products); each and every such organized structure, I say, in order that it may develop that function in a normal or natural manner, requires (in addition to the chemical agent or oxygen to which we have just been referring) the operation of another and an altogether distinct species of stimulus—requires, in a word, the operation of a stimulus *peculiar* to its own *species* of structure, and consequently, as I regard it, with propriety termed the *specific stimulus* of that structure to the discharge of its physiological function. Each distinct species of *simple* organizing agent (namely, each distinct link in the chain of progressively ascending organizing *atoms*), each such distinct species, I say, we have already seen required (in addition to the presence of the chemical agent, oxygen gas) presence of a species of stimulus (viz., "nutriment") *peculiar* to itself (and consequently a *specific stimulus*) to enable it to discharge its physiological function of conferring or imparting organization. The same—identically the same, I say, is also the case with regard to each of those organized residual products which is called upon to develop phenomena of animal life.

The precise nature of the relation in which, as it appears to me, these two species of stimuli (namely, specific and incidental) stand towards each other and towards the struc-

having been in a state of rest, he run with rapidity for a quarter of an hour, the following phenomena will occur, and mark particularly the *correspondence* in the occurrence of these phenomena—namely, he will find, 1st, an augmentation in the activity of the development of the phenomena of animal life (viz., increased action of nerves, muscles, &c.); 2nd, a strictly proportional augmentation in the activity of the respiratory process—viz., in other words, an inhalation, to a proportional extent, of an increased quantity of oxygen; 3rd, a strictly proportional augmentation of the animal temperature; and, finally (and the reader will please to mark this distinctly), and 4th, a *strictly proportional disorganization of organized structures* (as demonstrated by an analysis of the excretions). In other words, in proportion as inspired oxygen causes the disorganization of organized structure, in the same proportion is development given to—1st, vital phenomena, and 2nd, temperature.

ture upon which they act, while conjointly causing an organized structure to give manifestation to its physiological functions; the exact nature, as I regard it, of that relationship will, I say, more easily be made apparent to the general reader when I have attempted to lay before him the various *specific* stimuli which have been provided by Nature for the various organized residual products in question. The questions, then, which I would now desire to attempt to investigate, resolve themselves into the following two—namely, 1st, what is the specific physiological function of each of the organized residual products before us? and 2nd (*viz.*, the question proposed at the close of my last communication), and I say, 2nd, what is the *specific* stimulus of each of those residual products to the discharge of that physiological function?

The first question which naturally suggests itself on entering upon an investigation of the former of the two foregoing inquiries (*viz.*, what is the physiological function of the several structures before us?) is the following—namely, to which of the four orders of structure referred to—that is, whether to nervous tissue, to vascular structure, to muscular fibre, or to cerebral matter; to which, I say, of these four orders of structure should our attention, in the first place, be directed?

An answer to this question appears to me to be suggested in the *anatomic arrangement* of those four orders of residual product in man.

In contemplating the anatomic arrangement of the various organized structures which enter into the constitution of man, one of the facts which, as it strikes me, most forcibly arrests the attention, is the following—namely, that of the four orders of structure at present before us, the first named, or *nervous tissue*, has by Nature been placed in intimate and close anatomic connexion with *each* of the other three orders of structure referred to. In other words, an acquaintance with the anatomy of the human organization informs us that *that* organized structure, or residual product, to which anatomists have given the name *nerves*, has been placed by Nature in *direct physiological contact* with *each* of the three structures, or residual products, which have been respectively named muscular fibre, vascular structure, and cerebral matter. We see such arrangement has been adopted by Nature—we well know it cannot have been adopted without design; we are consequently led to inquire into that design. Why, we ask, is it *thus* that these tissues have been disposed? Wherefore is it that *this* has been their arrangement? In the recognition of the fact, that nervous tissue has been so placed with regard to the other three orders of structure, we recognize the fact of the *dependence* for something upon nerves of *each* of those other three orders of structures, and are led to inquire, *What is that dependence? what is that something?* Seeing, I say, that nervous tissue has been placed in close and intimate physiological connexion with vascular structure, with muscular fibre, and with cerebral matter, the questions are irresistibly forced upon the mind: *Why* has nervous tissue been associated with *vascular structure*? *why* has it been connected with muscular fibre? and *why* with cerebral matter? What, in a word, is the end or design to be accomplished by thus associating *each* of those structures with nerves? The primary answer to such questions must, as it appears to me, be this—namely, that the function of nerves (whatever it be) must be in some way connected (whatever that connexion may be) with the function to be discharged by *each* of those other three orders of structure respectively. The general answer, I say, to that question must, as I regard it, be obviously this—namely, that in the discharge of its specific physiological function (whatever be the nature of that function) nervous tissue must stand in some relation, be the nature of that relation what it may, to the functions respectively discharged by vascular structure, by muscular fibre, and by cerebral matter, whatever be the nature of the function which those structures are respectively designed to discharge. If such be the primary or general reply to that question, the next inquiry which suggests itself is this—namely, *what is that relation?* What, in a word, is the specific physiological function of nerves? Such, I say, is the question which, as it strikes me, anatomy

suggests as the one (in relation to the general inquiry at present before us) which might advantageously be the first to engage our attention. To an attempt at an investigation of that question, I shall consequently devote the remainder of my present communication.

The question before us is this: What is the nature of the relation which subsists between nervous tissue *generally* and the several other orders of structure with which nerves, in the discharge of their specific physiological function (whatever that be), have been placed by Nature in *direct physiological contact*? In other words, what is the specific physiological function of *that* final result of the regenerative process which, in the discharge of that function (whatever it be), has some *common* connexion with the function to be discharged by *each* of the other three final results of the regenerative process referred to? Such being the question before us, the two following inquiries at once suggest themselves to the mind—namely, 1st, is there *anything* (in relation to the discharge of their respective physiological functions) which is *common* alike to *each* and to *all* of those other three orders of structure with which we find nerves have been thus placed in connexion? and 2nd, if such be the case, is it in connexion with *that*—(namely, which is *common* to the discharge of their functions respectively), that nervous tissue is physiologically related to *each* of those tissues? Let me be distinctly understood. The two questions which, I say, naturally suggest themselves are these—namely, 1st, is there any circumstance or occurrence in connexion with the discharge of their respective physiological functions which is *common* (that is, which is the *same* for *all*), which, I say, is common alike to vascular structure, to muscular fibre, and to cerebral matter; inasmuch as we find that each of these structures has been associated with one common order of structure—namely, nerves? and 2nd, if there be any such circumstance or occurrence in relation to the discharge of their functions which is *common* to each and to all of those structures, is it in connexion with this common circumstance or occurrence that nervous tissue has been associated with those structures? To the former of these two questions, we are already in a position to reply in the affirmative. There is a circumstance or occurrence, in connexion with the discharge of their respective physiological functions (whatever those functions may be), which we have already, even antecedently to inquiring into the nature of those functions; which, I say, we have already ascertained to be *common* alike to each and to all of those structures. Each of those structures, we are aware, is called upon to develop what is termed “a phenomenon of animal life,” and we are further aware that in the development of such phenomenon, be its nature what it may, that structure must itself undergo the process of *degeneration*. Here, then, we recognize a circumstance or occurrence which (in connexion with the discharge of their respective physiological functions) is *common* to each and to all of those other three orders of organized structure with which we have just seen nerves have been placed by Nature in direct physiological contact—namely, each of those structures has to undergo the process of degeneration. The following question is then, I say, irresistibly forced upon the mind—namely, is it in relation to the process of their degeneration that nervous tissue has been associated with each of those other three orders of structure? I shall make an attempt to investigate this question.

In one of my former communications, I made an effort to *contrast* the nature of the organic functions performed respectively in the two departments of organic creation—namely, in the vegetable and in the animal kingdom, and that for the following purpose—*viz.*, in order to attempt to ascertain what it is, *organically* speaking, which constitutes the fundamental and characteristic distinction in *function* (mark particularly *distinction in function* in contradistinction to *distinction in structure*), what it is, I say, which, *organically* speaking, constitutes the fundamental and characteristic distinction in *function* between the vegetable and the animal world. That distinction in *function* I endeavoured to make it apparent to the reader is this—namely, that the *degeneration* of those organized residual

products, which I have termed the final results of the regenerative process, constitutes an *essential part* of the organic functions to be performed by the *animal*; whereas the *de-generation* of such organized residual products constitutes *no part* of the organic functions to be performed by the vegetable. In a word, the distinction in *function* between the animal and the vegetable is this—namely, the animal *de-generates* its finally or ultimately formed organized residual products; the vegetable *does not*. If, then, such be the distinction in function between the objects respectively of the two divisions of organic creation, *how* is the accomplishment of this distinction in function effected? *How*—that is, by what agency or means, is the degeneration of muscular fibre, for example, caused to take place in the animal, when we see that no such degeneration of woody fibre takes place in the vegetable, although that woody fibre be exposed, like muscular fibre, to the action of oxygen gas.\*

\* I trust that none of my readers will misunderstand my meaning in the above paragraph, or confound two considerations which are altogether distinct. It is, doubtless, a fact, that the *animal* tissues, such as muscular fibre, &c., have a tendency (resulting *exclusively* from the nature of *their own constitution*, and in no way dependent upon their association with any other structure whatever), it is, I say, a fact, that they have a tendency to undergo the process of disorganization when placed in circumstances under which the *vegetable* tissues, such as woody fibre, &c., may evince no such tendency whatever. The reader will bear in mind that it was with the *special design* of *their undergoing the process of degeneration within the animal frame*, that the *animal* tissues referred to have been constructed; consequently care has been taken by Nature that their constitution should be such as will admit of that process with *facility* taking place *so soon* as those structures shall be placed in the circumstances requiring their degeneration. No such degeneration of woody fibre, &c., is required to take place within the vegetable frame; consequently no such care has been taken with regard to its constitution. It is thus that from the fact of muscular fibre, &c., containing a large amount of the element *nitrogen*, as also from other constitutional peculiarities, to which it is unnecessary at present to refer; from the simple fact, I say, of its constitutional peculiarity (and depending upon no other distinction whatever) muscular fibre, &c., will doubtless undergo the process of disorganization (viz., run into decomposition) under circumstances under which the vegetable tissues (in the absence of this peculiarity of constitution) may retain their *organic* condition. If, for example, I remove a muscular fibre from an animal and at the same time a woody fibre from a vegetable, and expose both to the influence of oxygen gas, the former (from the peculiarities of its own constitution) will soon be reduced to the condition of mineral matter; whereas the latter (from a want of that constitutional peculiarity) may for an indefinite period retain the *organized* form. What I desire to impress upon the reader is this—namely, that the fact here referred to is entirely distinct from, and in no way interferes with that to which I have attempted to draw his attention in the above paragraph. I there refer exclusively to muscular fibre, &c., while constituting a portion of *living* man. That muscular fibre *does* undergo the process of degeneration *while* within the *living* man, is a fact that admits of no question; and the consideration which, in connexion with that fact, I have been above desirous of impressing on the reader is this—namely, that so long as his voluntary muscles, for example, constitute a portion of a *living* man, those muscles *do not begin* to undergo the process of degeneration (notwithstanding their constitutional peculiarity referred to) *until they commence the discharge of their function*; in a word, until they have been acted upon by *voluntary nerves*. *Until* those voluntary muscles have been acted upon by voluntary nerves, they retain the condition of muscular fibre possessed of *quiescent* vitality. When they are acted upon by voluntary nerves, they commence the discharge of their function; when their function has been *completely* discharged (namely, when they have lost all muscular contractility), they exist in a *degenerated* state; and in such state can with facility be reduced to the condition of *mineral matter*. The *complete and total* disorganization, however, of muscular fibre (that is, the reduction of *all* its components to the condition of *mineral matter*) does not (for important reasons) take place *within* the animal frame. How far *involuntary* muscles and vascular structure have or have not been placed under the control of *nervous influence* as their specific stimulus, I shall presently attempt to investigate.

How is this so? Upon what does it depend? It *must*, as I regard it, depend upon some distinction in *structure* between the vegetable and the animal. What, then, is that distinction in structure? There *must*, I say, as it appears to me, have been some *structural* distinction made between the vegetable and the animal kingdoms in general to provide for the accomplishment of this requisite or essential distinction in function. Let us then inquire *what it is*, physiologically speaking, which constitutes the fundamental and characteristic distinction in *structure* between the vegetable and the animal; and depend upon it if such distinction be truly ascertained, we shall not be far from a knowledge of the *specific* agency provided by Nature for causing the *de-generation* of muscular fibre, &c. It is needless for me to acquaint my readers that the distinction in structure referred to is this—namely, that to the *animal*, exclusively and alone, belongs what is termed “*a system of nerves*.” Here, then, we learn *why* it is that nervous tissue has been appended to the *other* organized structures referred to—here we have disclosed to us the nature of the *specific physiological function of nerves*. That function, as I regard it, is this—namely, to stimulate to the discharge of its specific physiological function each of those other orders of structures respectively with which such nerves have been placed by Nature in direct physiological contact. In a word, to be the *specific* stimulus of those other structures to the discharge of their function.

I shall for perspicuity recapitulate the foregoing observations. We see, 1st, that the organized residual products, named vascular structure, muscular fibre, and cerebral matter, *do* undergo the process of degeneration in the *animal* as a *necessary part* of that animal's function; and that the organized residual product, named woody fibre, &c., *does not* undergo the process of de-generation in the vegetable, but that the degeneration of such woody fibre, &c., forms *no part* of that vegetable's function. We see, 2nd, that the organized residual products, named vascular structure, muscular fibre, and cerebral matter (which *do* undergo the process of degeneration in the animal), *have been* respectively placed in close and intimate physiological connexion with *nerves*; and that the organized residual product, named woody fibre, &c. (which *does not* undergo the process of degeneration in the vegetable), *has not* been placed in physiological connexion with *nerves*. We see, 3rd, that the fundamental and characteristic distinction in *function* between the animal and the vegetable is this—namely, that in the *animal* (and *not* in the vegetable) the degeneration of organized residual products must of necessity take place; and that the fundamental and characteristic distinction in *structure* between the animal and the vegetable is this—namely, that the *animal* (and *not* the vegetable) has been provided by Nature with *nerves*. From these facts, I feel warranted in deducing the following conclusion—namely, that nerves (whatever additional function, whether imaginary or real, may be attributed to their agency) take some part in *causing the degeneration* of those organized structures with which they have been placed in physiological contact.

In one of my early communications (MEDICAL PRESS, Vol. xxvi., p. 149), I ventured to solicit the reader's attention to the following words, and to urge upon him to make himself fully convinced of their truth—viz., “The function of the vegetable is *single*—namely, the generation of structure; and the *specific stimulus* to the discharge of that function is *nutrient matter*.” My motive for then urging these words upon his attention was this—namely, that he might *now* be enabled, with greater facility and clearness, accurately to recognize (what to me appears to be) the true nature of the *specific* physiological function of nerves, and to comprehend the full force of the following statements—viz., the function of the *vegetable* is *single*—namely, the *generation* of structure; and the *specific stimulus* to the discharge of that function is *nutrient matter*. The function of the *animal* is *twofold*—namely, 1st, the *generation* of structure; and the *specific stimulus* to the discharge of that function is “*nutrient matter*,” and 2nd, the *de-generation* of the structures *last* formed, or *finally*

generated; and the specific stimulus to the discharge of that function is (for those structures which have been physiologically associated with nerves) the influence shed upon such structures by nerves.

I shall postpone any further observations upon this subject till my next communication. In the meantime, I would beg of the reader to reflect upon the nature of the *physiological relations* (viz., to the structures with which they are *anatomically connected*) of those nerves with the functions of which he is familiar.

(To be continued.)

## ON SYPHILITIC IRITIS IN INFANTS.

By JAMES DIXON, Esq., F.R.C.S.,

Surgeon to the Royal London Ophthalmic Hospital.

INFLAMMATION of the iris, although an extremely rare form of infantile syphilis, has occasionally come under the notice of those who have had extensive opportunities for observing ophthalmic disease among the poor; and accordingly we find it alluded to in the works of Lawrence, Jacob, and Walker.

The first mentioned of these writers gives only slight details of his cases. One patient was nearly a year and a half old when the iritis came on, which was of a very "mild form; . . . the iris lost its brilliancy, and assumed a dark tint; the pupil was a little contracted; there was some redness of the sclerotica, and of the upper lid, and slight intolerance of light." The tendency to effusion of fibrin—the peculiar mark of syphilitic iritis in the adult—appears to have been altogether wanting. In the other patient an eruption showed itself a few weeks after birth, and a few weeks later severe inflammation of the eyes came on. Mercury arrested this, as it had arrested the eruption. Some weeks afterwards, "both pupils were fixed, and moderately contracted. An opaque body—not a cataract—was seen behind one; the other was clear. Both eyes were blind." Walker, in his "*Oculist's Vade Mecum*," briefly mentions the occasional occurrence of syphilitic iritis in infants; but in the *Provincial Medical and Surgical Journal* says he had seen about six cases of iritis in infants within as many years; he does not, however, expressly state that any of them had a venereal origin. Two of these cases of iritis he relates at length, and I shall have occasion more particularly to refer to them when speaking of the treatment of the disease. Evanson and Maunsell, with their very large experience of infantile complaints, saw but one case of syphilitic iritis—namely, in a child a year old. The father was the subject of syphilis, but the mother was not known to have been similarly affected. Dr. Taylor has lately seen iritis in an infant, but he considers the disease to have originated from the irritation of teething.

A well-marked case of syphilitic iritis, occurring in a child only four months old, has lately presented itself at the London Ophthalmic Hospital, and another came under my notice, four years ago, where nothing but the mother's own testimony was wanting to establish positively the specific origin of the disease.

Case 1.—Wm. T. J.—, aged four months, was brought to the hospital February 19, 1852. He was a well-grown child, lively, and taking the breast well, and this had been his character, his mother said, from his birth. A week before coming to the hospital the mother noticed that the sclerotic of the right eye looked "pinkish," and the child seemed rather to shun the light. Both of these symptoms, however, had passed off when I saw him, and the absence of sclerotic redness was remarkable, when compared with the large amount of fibrinous effusion in the anterior chamber. The cornea was clear; the upper half of the iris (of a gray colour) not perceptibly altered in structure; the lower half was completely hidden by a nodular mass of deposit, of a pale, Naples-yellow tint, which came in contact with the cornea, and completely filled the anterior chamber as high up as the middle of the pupil; the latter was rather dilated

than contracted, misshapen, uninfluenced by light, and rendered indistinct in its outline by a film of half fluid deposit, which encroached on the capsule.

At this time nothing was known about either the child or mother having had syphilitic symptoms; and the absence of sclerotic or conjunctival redness led me to regard the deposit in the anterior chamber as most probably of serofulous nature. As the child's bowels were in good order, nothing more was ordered on this first visit but five minims of Battley's liquor cinchonæ twice a day, and fomentation locally in the event of the eye becoming red or irritable.

23rd: The eye to-day looked much worse; the upper part of the iris, previously healthy in appearance, had assumed a dirty tint, and was seen through a turbid aqueous humour, looking as if recent fibrin were diffused through it, and rendering the form of the pupil almost indistinguishable; the left pupil had also become slightly irregular, and the aqueous humour had assumed, though in a less degree, the turbid appearance so remarkable in the other eye; still there was hardly any redness of either sclerotic.

I now obtained the following account from the mother, at present a remarkably healthy-looking young woman. She said that about six weeks before she became pregnant of this child, her husband communicated to her the venereal disease. She had sores and enlarged inguinal glands, and was under treatment as an hospital out-patient for five weeks, towards the end of which time "pimples" appeared on her face and arms. Both sores and eruption yielded to a moderate course of mercury. She said she had no sore-throat, and there are no scars to be seen about the palate or tonsils. When the child was about a month old, he was attacked with a moist, dusky-red eruption over the greater part of the body. A medical man, to whom the child was taken, administered powders (probably mercury-with-chalk,) and in about five weeks the eruption disappeared, with considerable desquamation of cuticle.

The increased tendency to deposit in the child's right eye, and the extension of disease to the left one, together with the history which had been obtained from the mother, showed that no time was to be lost in administering mercury; and accordingly a grain of mercury-with-chalk was ordered to be given night and morning, the liquor cinchonæ being continued as before.

26th: No extension of disease in the left eye; indeed the aqueous humour seems, if anything, rather less turbid; in the right eye the yellow deposit is no longer aggregated together in a mass at the lower part of the anterior chamber, but seems as if softened and undergoing solution in the aqueous humour, so that the position of the pupil can hardly be traced through the cloudy medium. The child's health continues good, his bowels are moderately open, and he takes the breast well.

March 1st: Less deposit in the right anterior chamber; the outer circumference of the iris is more distinctly seen, the fibrin having collected in a denser mass about the pupil, which is even more obscured than on the last visit; the left pupil is rapidly clearing, and becoming more regular in its outline. 4th: Things have gone on improving during the last three days; more and more of the outer part of the right iris is coming into view, and the denser portion of the fibrin is seen lying in the pupil; the left eye is almost well. 11th: The iris has regained its natural colour and texture, except near the upper and outer edge of the pupil, where some enlarged veins are visible, and a minute patch of blood is seen extravasated among the fibres of the iris; the pupillary margin is jagged, and adherent throughout to the capsule of the lens, which is overspread with an opaque layer of pale yellow fibrin, in the centre of which is a raised nodule of the same deposit; the left eye is well; the pupil round and clear; and the child enjoys good sight with it. 25th: The left eye remains perfectly healthy. A considerable change has taken place in the right; much of the fibrin which was filling the pupil has been absorbed, and only a very thin, smooth layer overspreads the capsule; the edge of the pupil has lost its jagged outline; the lens comes a good deal forwards, so as very much to diminish

the anterior chamber; the veins of the iris are still here and there visible; the child's general health is very good, and his skin is losing a certain dusky tinge which it had when he was first put under treatment. He still continues to take a grain of mercury-with-chalk twice a day.

*Case 2.*—*Mary Ann W.*—, aged three months, was brought to me from Croydon, November 13, 1848. The child was strong and healthy-looking at birth; but when about seven weeks old, a brownish-red, scaly eruption appeared over the greater part of the body, which the medical man to whom the mother applied considered to be syphilitic, and for which he prescribed some mercury-with-chalk and one-tenth of a grain of iodide of potassium twice a day.

About a fortnight after the eruption broke out, the mother noticed that the child, who hitherto had seen quite well, had “a pearly appearance” in each pupil, and seemed to be nearly blind. I found the eyes in the following condition:—Both globes rather unsteady, rolling a little from side to side. There was no redness of either sclerótica. All the eye-lashes had fallen off. The left iris (gray) was dotted over, throughout its lower half, with little grayish-white masses, almost like grains of coarse sand, and the inner portion of the iris was streaked with lines of a similar tint, passing vertically, as if fibrin had trickled over the part, and left a track behind. The pupil was contracted, and fringed with the same kind of grayish-white deposit as appeared on the surface of the iris; adhesion of the pupillary edge to the capsule of the lens seemed to have taken place, inasmuch as atropine, which dilated the right pupil, had no effect on the left one. The body of the lens was a little cloudy.

The right iris looked healthy throughout, and the body of the lens clear; but on the capsule, just skirting the outer edge of the pupil, was a chalky-white, crescentic patch; there was, however, no adhesion of the iris at this point, for when atropine was used, the patch became separated to some distance from the pupillary edge.

The child's mouth was affected with aphthæ, and a scaly eruption covered the face. On the lower limbs were patches of a coppery tinge, extending upwards to the belly and downwards below the knees, with desquamation of the cuticle.

Although both parents denied having had venereal disease, the condition of the child convinced me that its symptoms were of syphilitic origin, and accordingly I ordered two grains of mercury-with-chalk, to be taken night and morning.

November 20th: The eruption has nearly faded away, and the mouth is free from aphthæ; the dots on the left iris, and the crescentic patch on the left capsule, look smaller. Ordered mercury-with-chalk two grains every night, liquor cinchonæ five minims twice a day, in milk. 27th: All eruption gone; the child takes the breast well, and is improved in general appearance; the grayish dots and streaks on the left iris have entirely disappeared, and the whitish line of adhesion between the pupillary edge and the capsule exists only towards the upper and outer part; in the right eye, the chalky-looking patch on the capsule is reduced to two small dots, marking the horns of the crescent.

December 4th: The child's health is excellent; the pupil of the right eye, when dilated with atropine, is very slightly irregular, owing apparently to some little adhesion of its outer edge to the capsule. Every trace of the white patch on the latter is gone, and the pupil is quite black and clear; the left iris now looks healthy in its texture, but there is irregularity and immobility of the pupil, which has not expanded under the use of atropine, and a slight milkiness of the lens remains. The child seems to have regained good sight in right eye, and follows white objects, such as a pen or piece of paper, moved to and fro before it.

January 1, 1849: Two grains of mercury-with-chalk have been taken every day up to the present time. The left pupil is still rather smaller than the right, but no synechia can be detected. The child is in good health, and notices objects well. It seems to see the right eye more than the left. The eye-lashes have grown again, and are thicker than

ever. The medicines were continued in diminished doses for about three weeks after this date.

March 25, 1850: The child is well-grown and healthy; there is no synechia to be seen in either eye; the only morbid appearance is a slight cloudiness of the left lens. The steady improvement, under the use of mercury, without any local depletion or counter-irritation, seems to confirm the belief that both of these cases were really of venereal origin. In Case 2, one link in the chain of evidence is wanting—namely, the mother's admission that she had suffered from venereal disease; but no one who has had much experience in treating syphilitic patients will allow the absence of this testimony entirely to set aside the positive proof afforded by well-marked morbid phenomena.

At the beginning of this paper I spoke of the rarity of iritis as a form of infantile syphilis. Mr. Lawrence, writing in 1841, says—“Numerous children labouring under this disease (syphilis) have come under my observation, but iritis has occurred in two instances only.”

In the nine years during which I have been attached to the London Ophthalmic Hospital, the annual number of out-patients has progressively increased from 6000 to 11,000, and yet the two cases above related are the only instances in which syphilitic iritis in infants has come under my own notice. The very slight degree of redness in the sclerotic of infants attacked with this form of inflammation is a fact which did not escape the notice of Dr. Jacob. In Case 1, above related, there appears to have been some little redness of the eyeball at the first onset of the inflammation; but, during the time when effusion of fibrin was going on, the sclerotic was, as nearly as possible, of healthy appearance; and, in Case 2, it was cloudiness of one of the child's lenses, and its impaired sight, not any redness of the eyeball, which drew the mother's attention to the disease. Yet, notwithstanding this seemingly low stage of the inflammatory process, organization of fibrin was rapidly proceeding to the formation of opaque adhesions between the iris and capsule of the lens.

Walker, on the contrary, asserts, that iritis in infants is usually accompanied with “considerable intolerance of light and lachrymation.” There are several points in this treatment which call for remark. He advises leeches to the palpebræ as “useful in most cases—in such numbers as are suitable to the age and constitution of the child.” The “constitution” of the children brought as patients to the eye-hospitals of our great towns, is seldom so robust as to allow of their losing blood without injury; and the occasional application of two or three leeches to the lids, as Walker advises, could influence but little the deep-seated tissues of the iris, choroid, and retina, so as to lessen the disposition of their vessels to exude fibrin.

He goes on to say, that “purgatives, and in some instances even nauseants, should be freely administered in the first instance.” Now, that the contents of the child's bowels should not be allowed unduly to accumulate is self-evident; but the use of any medicines likely to nauseate, and unfit the stomach for retaining food, I cannot but regard as mischievous. In no patients do we find fibrinous effusions on the iris and in the anterior chamber more abundant than in those whose vital energy has been depressed below the natural standard.

Walker next adverts to the use of mercury:—“Small doses of calomel, or of mercury-with-chalk, should be administered without delay, and continued until the progress of the disease has been arrested, or the system has been brought under the influence of this powerful agent.” With this opinion I entirely agree; but let us see what he considers to be “small” doses. In Case 1, an infant seven months old, two grains of calomel were given twice a day during five weeks; then once a day for two months longer; at the end of that time the dose is resumed night and morning. And what is the result? The last report says: “No alteration of the eye was observed after this time, the pupil remaining permanently contracted, and the capsule opaque.” The eye, in other words, was useless. This patient had had no eruptions, nor was there any suspicion, apparently, that the iritis was of syphilitic origin, and yet

this enormous quantity of calomel was administered; while in Case 2, where eruptions, of supposed venereal origin, had attacked a child six months old, the accompanying iritis, although attended with as great a tendency to fibrinous effusion as in Case 1, was treated with moderate doses of mercury-with-chalk—two grains night and morning. After less than three weeks of this treatment, “the inflammatory action had entirely ceased; the pupil was moderately dilated, and apparently fixed; the iris appeared dull, but the tubercles (fibrin) had disappeared from its surface . . . the blotches on the forehead were much diminished, the bowels more regular, and the general health better.” So that (other things being to all appearance equal) the case treated with moderate doses did better than that where such large quantities of calomel had been given.

A few words in conclusion, on the use of belladonna. Walker says—and similar advice is given by most ophthalmic writers when treating of iritis—“Belladonna should be applied freely around the orbital region, so as, if possible, to keep the pupil in a state of expansion.” And again,—“Belladonna must be regarded as the paramount local remedy.” I have elsewhere drawn attention to the inutility of belladonna when the iris is in a state of active inflammation. Such an iris does not move when belladonna is applied to the eye. The natural movements of the healthy iris are extremely delicate, and cannot be properly performed unless there exists a certain balance of pressure in the fluids of the globe. Over-distension of the anterior chamber with aqueous fluid, extensive loss of vitreous humour, undue pressing forwards of the lens, are all causes which will arrest the proper movements of the iris, even when its structure is not appreciably altered; but when this is in a state of inflammation, its veins distended, and fibrin infiltrated into its tissues, no application of belladonna will alter the dimensions of the pupil to any considerable extent. This is a fact which any one treating a case of active iritis can verify for himself; and when once the pupil is filled with effused fibrin, dilatation, even if “possible,” will avail nothing, unless such a change in the patient's blood be effected as will check the pouring out of fibrin, and promote the absorption of that already effused. Iritis (apart from the concomitant inflammation of choroid and retina) destroys sight—not because the edge of the pupil becomes here and there united to the capsule of the lens, or because the pupil is rendered smaller; such adhesions would affect only the proper adjusting changes in the size of the pupil: what we fear in iritis is, that the area of the pupil should get filled with fibrin, which, becoming a firm, opaque membrane, would entirely shut up the aperture.

Now let us see whether my assertions are borne out by the result of Walker's cases. In the first, belladonna appears to have been constantly used during more than four months, and yet the conclusion of the report describes the pupil as “remaining permanently contracted, and the capsule opaque.” In the second case, when the eye was first seen, the pupil was “circular, and not much contracted.” Belladonna was constantly used for more than a month, and yet at the end of this period the pupil is stated to have been “moderately dilated” (nearly equivalent to “not much contracted”), “and apparently fixed.”

The inefficacy of belladonna in acute iritis was forced upon my notice by the fact that whenever I saw a patient, who, any considerable time previously, had been the subject of that disease, I never found a pupil fixed by synechia in a condition of permanent dilatation; and yet this ought sometimes to happen if belladonna acted in the manner its advocates allege. Indispensable as this substance is for attaining a correct diagnosis of morbid changes posterior to the iris, I look upon its employment when that structure is inflamed, not only as ineffectual towards attaining the end proposed, but as likely, in some measure, to draw off the surgeon's attention from that all-important agent, mercury, which alone, as far as we yet know, has the power of checking those inflammatory changes in the eyeball comprehended under the single term, iritis.—*Lancet*.

#### CASE ILLUSTRATING THE PATHOLOGY OF SECRETION OF PUS IN THE LIVER—SUPPURATIVE PORTAL PHLEBITIS.

By Dr. SWETT, Physician to the New York Hospital.

THE following paper presents the history of a case of a rare form of disease, the diagnosis of which must be attended frequently, if not generally, with considerable difficulty. The case is also interesting as illustrative of the general symptoms associated with suppurative phlebitis:—

A gentleman, aged 58, had generally enjoyed good health, except that fifteen years ago he had an affection of his stomach, which was suspected at the time to be of a cancerous nature, but from which he perfectly recovered by visiting the Sulphur Springs of Virginia. During the eighteen months also, preceding the fatal sickness, he had noticed occasionally a slight tendency to diarrhoea, which did not interrupt, however, his usual good health. Indeed, his friends, just before his last sickness, regarded his health as unusually good. During the early part of the autumn, he had been somewhat exposed for two or three weeks to the malarious influence. On the 10th of October, he attended to his business as usual during the morning, but in the afternoon he returned home feeling unwell. In the evening he sent for his physician, who found him complaining of a muddy feeling across the forehead, of nausea with slight vomiting of bilious matter, and of slight colic-like pain in the abdomen; his skin was rather feverish, and his pulse about 100. He took some purgative medicine containing blue-pill, which operated well, producing healthy, natural stools, and affording relief. On the next day he continued to be slightly feverish; his pulse was still accelerated, and his skin began to assume a yellowish tinge. He complained of a sensation of inward fever, as he called it, which he referred to the epigastric region. About this time also he began to experience chills.

The jaundice continued to increase, and the chills returned irregularly, sometimes three or four times in a day, followed by increased heat, which soon terminated in profuse perspiration. There was no complaint of pain, nor of tenderness on pressure anywhere, and especially over the region of the liver, which was carefully examined. The cerebral functions, as well as those of the chest, were quite undisturbed; the pulse was generally below 100; there was some appetite; the patient enjoying a little chicken soup, and tea with cracker. The bowels were kept regular by simple purgatives and by injections.

About the 22nd of October, two weeks after his illness commenced, the chills assuming more regularity, and the remission of the fever seeming to be more distinct, and there being no local pain or uneasiness—indeed, no evidence of any local affection except the jaundice, and with this the stools were quite natural in appearance, ten grains of the sulphate of quinine were administered, and afterwards five grains every four hours, until three doses had been taken. This treatment was at first followed by marked relief; the next day he took five grains every four hours, until he had taken three doses; the third day he took but two doses, as the improvement first experienced from the use of the remedy did not continue, and the chills had returned. He also complained of deafness and of ringing in the ears.

A temporising plan of treatment was now pursued again. The patient used effervescent draughts, and took with some relief a bowl of chicken soup. The bowels were regulated by simple means; a little sulphuric acid, and afterwards the nitro-muriatic acid, which the patient enjoyed very much, was prescribed, and a foot-bath of the same was used at night. There was still no complaint of pain in the region of the liver, and firm pressure, especially upward under the ribs, in the right hypochondriac region, and percussion in the same region, discovered no tenderness. The pulse continued to range at about 100, but the chills returned irregularly, followed by increased fever, and rapidly by profuse perspiration. The yellowness of the skin was diminishing. About the 28th of October,

the febrile symptoms having again assumed a more regular type, quinine was again prescribed, but with no benefit. It was therefore omitted, and the expectant plan of treatment again adopted.

This plan of treatment was continued until the 3rd of November. The patient when asked how he felt, invariably answered "perfectly comfortable." There was still no pain or tenderness on pressure over the region of the liver; the jaundice was diminishing; the pulse was about 100, soft and regular; the patient slept tolerably at night; his tongue was slightly coated, but he took nourishment with a certain relish; his intellect was perfectly clear, and he was now quiet and composed. The chills had again assumed more regularity. Every afternoon, at about half-past three, a chill would occur, followed by fever, and rapidly by profuse perspiration; but during night the face was flushed, and the skin hot and dry. Towards the morning the excitement seemed to abate, and the pulse became less frequent, and from this time until three or four o'clock in the afternoon, the patient was more comfortable. Still a slight degree of chilliness would recur, irregularly, at different periods of the day. It was determined to try again the effect of quinine. A grain every hour for three successive hours was prescribed, when the chill recurred at the usual hour, three p.m. It was administered again in the same doses, commencing at two p.m. of the 4th of November, when the paroxysm of the preceding afternoon had subsided. It was continued through the day, and at three p.m. a full dose of laudanum was administered. The chill did not recur, nor ever afterward.

The quinine was omitted as soon as the chill had ceased, on the morning of the 6th of November; and the case was again treated by the expectant plan. A little brandy was allowed, and beef-tea was directed to be given. On the evening of the 6th of November, there was some vomiting; the abdomen was becoming tympanitic, and then the prostration, which had been great, became more decided. Still there was no abdominal pain or tenderness, and there were two natural stools following a simple injection. The tendency to sinking continued during the night, and on the morning of the 7th of November, the patient was decidedly worse. His pulse was feeble and irregular, the skin was inclined to be cold, his features were altered, and he vomited at times. Still his intellect was perfectly clear, his manner composed and tranquil, and he experienced no abdominal pain or tenderness, although the tympanitis continued. During the day, with the use of moderate stimulation, he rallied gradually. His pulse became regular and improved in strength, and had fallen to 104; the temperature of the skin was quite natural; there was no tendency to chill or perspiration. Once, during the afternoon, he complained of pain in the right side of the abdomen, which was relieved by pressure. The succeeding night was passed comfortably; the patient slept a good deal, awaking at intervals; and on the morning of the 9th of November, he was apparently more comfortable than the day before; his pulse had fallen to 96, and was regular, but rather feeble; there was no febrile excitement; the tongue was moist, and but slightly coated; the stomach was tranquil, and there was no complaint of pain. The patient gave his oft-repeated answer:—"I am perfectly comfortable." But about the middle of the day, the mind began to wander a little, and a tendency to restlessness ensued, with hicough. A severe attack of abdominal pain ensued, which was relieved by a mustard plaster. The abdomen was still distended, and it felt very hard on pressure, which, however, produced no decided pain. During the evening the patient gradually sank, and died during the night.

*Autopsy.*—The evidences of general peritonitis existed. Lymph and sero-purulent matter were effused in the peritoneal cavity; there was but little lymph effused on the surface of the liver or of the spleen, and none upon the surface of the stomach; the liver was not enlarged; it was of a dark and rather greenish hue, and somewhat flabby; the portal vein was hard and firm, and when examined was found filled with lymph, partly firm, partly

broken down into a grumous detritus. The branches of this vein, as they ramified through the liver, were filled with healthy pus. The hepatic veins were not affected; the substance of the liver was also quite healthy; the mesenteric vein supplying the small intestines was also filled with pus, and the mesentery itself was much thickened, and its cellular tissue contained numerous collections of pus. The stomach and the intestinal canal, examined as low as the rectum, were quite healthy, except that the coats were somewhat thickened. The other abdominal organs were also healthy. The lungs contained a few cretaceous tubercles. The brain was not examined.—*New York Medical Times.*

#### SPONTANEOUS CURE OF OVARIAN TUMOURS BY DISCHARGE OF THEIR CONTENTS THROUGH THE FALLOPIAN TUBES.

By Dr. ROBERTSON.

THE following case occurred to Dr. Robertson, Physician to the Hitchin Infirmary, and to the notes of which he had an opportunity of adding the post-mortem appearances:—Mrs. —, a delicate, strumous, married young woman, consulted me in June, 1847, regarding her enlarged abdomen. She said that now her abdomen had enlarged gradually for some months, but more rapidly within the last two months; it was as large as, and of similar appearance to, that of a pregnant woman at her full time. She had menstruated regularly; did not think she had ever been pregnant; passed but a small quantity of milky-looking urine. A fluctuating tumour filled the pelvis, pressing on the rectum and vagina; the uterus was distinguishable, high up, but small. A catheter was passed: the bladder was empty. She told me she had a similar swelling about a year before this time, which ended by an immense discharge from the vagina. She attributed this first attack to over-exertion in walking. Her health had been very delicate for some years; she suffered much from dysmenorrhœa. A few days after this, whilst in bed, suddenly a great discharge of most abominably stinking, white, slimy fluid, with a quantity of white and greenish flakes and pieces of bladder-like substance floating in it, enough to fill two full-sized chamber-pots, took place per vaginam. The abdomen resumed its natural size; the discharge in four months diminished to a mere weeping. She now had symptoms of phthisis, and died in September, 1848. On making examination after death, we found old adhesions plentiful about the lower abdominal and pelvic regions, attaching the various viscera together. In the right ovary was a cyst as large as a medium-sized orange, with a very ragged interior, containing some fluid like that discharged; it was much corrugated and collapsed, and communicated with the Fallopian tube, on which were two other cysts of the same appearance as the other, but about one-fourth the size; there was also one cyst, unruptured, as big as a small orange, filled with glairy fluid, in the same ovary. In the left ovary was a cyst of precisely the same appearance as that first described, but empty, communicating with the left Fallopian tube. The Fallopian tubes were dilated; the uterus was sound, but harder than usual throughout.

The following is somewhat similar, but not so complete:—Mrs. G—, a cachectic, strumous married woman, aged 36, not having been pregnant, and who menstruated regularly, observed about sixteen years ago (this was in December, 1848) a fulness in the right iliac region, which had since gradually become greater, and which on examination presented the usual signs of an ovarian tumour, she being at this time as big as if about seven months gone with child. In February, 1849, she found herself one morning, on waking, in a pool of "blood and matter" up to her shoulders, which had escaped per vaginam. A considerable discharge continued for some time, but in six months had nearly ceased; her general health had improved, and the abdomen resumed its natural size. She is now (September, 1851) in pretty good health, and the contents of the pelvis appear healthy.—*Lancet.*

## CONTAGION OF SECONDARY SYPHILIS.

THE idea, which now appears to be gaining ground, that secondary syphilis is communicable, has been recently taken up by Dr. Waller, of Prague, in an elaborate memoir. The author herein expresses his conviction, that this form of the disease is contagious, upon the following grounds:—

1. That it is not uncommon to meet with mucous tubercles in persons who have neither had chancre nor gonorrhœa, in whom, in fact, these flat tubercles were the first manifestation of syphilis. 2. That other forms of syphilis, usually denominated secondary, may be the first symptom of the disease. 3. That secondary syphilis may be perpetuated by the agency of the blood.

Several clinical facts are adduced which bear upon these propositions, but we shall pass on to the actual experiment by inoculation, as affording the most conclusive evidence in favour of the author's assumptions. These experiments were of two kinds; in one series the inoculation was from the secretions of the mucous tubercles, in the other the blood itself was the medium of inoculation.

The first kind of inoculation was performed upon a young man who had never been the subject of chancre or gonorrhœa, by means of punctures on the thigh, to which lint, dipped in the secretion, from a patient labouring under condylomata, was applied; the result was, the production of numerous tubercles upon the site of the punctures. Twenty-seven days after the first appearance of these, syphilitic maculæ began to show themselves on the abdomen, and in a few days more the whole body was covered.

The second kind of inoculation was made upon a lad, aged 15, the subject of lupus, who had never had syphilis. On the 27th of July some blood was drawn, by cupping, from a female who was labouring under syphilitic maculæ and tubercles, and was immediately applied by means of lint to some scarifications on the thigh of the boy. Neither inflammation nor suppuration ensued, and in three days the incisions were completely healed. On the 31st of August—i.e., twenty-four days after inoculation, two tubercles, the size of a pea, were observed upon the site of the punctures; these increased in size, coalesced, and became covered with thin scales. Eventually ulceration took place. On the 1st of October, sixty-five days after inoculation, and thirty days after the appearance of the tubercles, an eruption, of a distinctly syphilitic tint, came out upon belly, back, and chest, and speedily became general.

From these experiments the author deduces the following propositions:—1. Both primary and secondary syphilis are inoculable. 2. Contrary to the doctrine of M. Ricord, that secondary phenomena are always preceded by chancre, it is established, that in certain cases the symptoms usually considered as secondary, may be the first manifestation of the disease. 3. Neither can we receive, as strictly true, the maxim propounded by M. Ricord, that inoculation furnishes a means of diagnosing primary from secondary syphilis.—*Prov. Jour.*

## HÆMORRHAGE FROM TOOTH-DRAWING.

READING in your valuable journal of April 24th, a case in which an infant died from hæmorrhage of the gums after scarification, I am induced to relate a case which occurred in my own practice, with a gentleman, for whom I extracted the fangs of a first molar, some three or four months since, when profuse bleeding ensued; and although all the styptics were used, and plugs of lint forced into the cavities, yet it continued for seven hours. I now thought it quite time to devise some means, if possible, to arrest it, particularly as my patient was becoming weak; and it struck me that gutta percha would be just the thing. It scarcely required or had a minute's consideration before I had a piece well softened in hot water, which I moulded over the wound, down on either side of the alveolar ridge, leaving it high enough for the upper teeth to press firmly on it; this had the desired effect. The hæmorrhage was immediately arrested, and my patient retired to rest to be annoyed no more with it. My impression is, that the same means may be used in numberless instances for the same purpose, requiring only a little ingenuity to adapt it to the particular case.—*Mr. Rowney, Dentist, of Lynn, in Lancet.*

## REVIEWS AND NOTICES OF BOOKS.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. By J. MOORE NELIGAN, M.D., &c. &c. Dublin. 1852. pp. 439.

As Irish journalists it gives us much pleasure to bring under the notice of our readers another practical work in addition to the many which of late years have issued from the Dublin School. Some of our contemporaries are pleased to refer to certain deficiencies on this side of the water, and to congratulate themselves on what an American would call their "go-a-headativeness," but we defy them to produce an equally numerous list of equally valuable works in all the practical departments of medicine.

Dr. Neligan is already well known to the profession by his excellent work on *Materia Medica*, and we have great pleasure in saying that the present volume will add to his reputation as a practical physician. It is very well written, and gotten up in a style that will not lose by comparison with books published in England or Scotland.

Fully agreeing with Dr. Neligan in his objections to all the natural classifications that have been attempted, we think also that his artificial one is the most simple and comprehensive we have seen. It is as follows:—

## Order.

## Genera.

1. Exanthemata.... Erythema, erysipelas, urticaria, roseola.
2. Vesiculæ, ..... { Eczema, herpes, pemphigus, rupia, scabies.
3. Pustulæ ..... Acne, impetigo, ecthyma.
4. Papulæ..... Lichen, prurigo.
5. Squamæ ..... Psoriasis, pityriasis.
6. Hypertrophia, { Ichthyosis, molluscum, stearrhœa, elephantiasis, verruca, clavus, callositates, condylomata, nævus.
7. Hæmorrhagiæ... Purpura.
8. Maculæ..... Vitiligo, epiphis.
9. Caneroides..... Lupus, kelois.
10. Dermatophyta... Porrigo, sycosis.

With two supplementary groups—the syphilides and the diseases of the hair and nails.

The descriptions of the different diseases are carefully and graphically written, evidently from the author's own observation; but whilst this is the foundation, we do not find that he has been negligent in doing full justice to other observers. We are glad to see also that the differential diagnosis is well brought out. Few things puzzle a beginner more than the exact distinction between similar diseases of the skin, and mistakes by even advanced practitioners are not very uncommon. As an illustration, we will quote the diagnosis of eczema:—

"The diagnosis of eczema in its advanced stages, and in some of its local forms, is not unattended with difficulty. Eczema simplex may, at its origin, be mistaken for herpes, but the vesicles in the latter are larger, more distinct from each other, and occur in patches, always well-defined, and often of small extent. When it appears on the fingers, the serious mistake of confounding it with scabies is not unfrequently made, and thus much mental annoyance may be caused, not alone to individuals, but to families, owing to the dread and anxiety with which that eruption is viewed by all. Even at their commencement, they are, however, readily to be distinguished, the vesicles in itch being solitary, large, and conical, and becoming rapidly purulent. The tingling burning heat of eczema is also very different from the intense itching of scabies; and by careful examination, the itch-insect, the existence of which is an unfailing diagnostic sign, may be discerned in the latter. In fevers and other diseases in which profuse sweating occurs, a vesicular eruption, which, from the cause by which it is produced, is termed *sudamina*, appears not unfrequently on the cutaneous surface, and might be mistaken for eczema simplex; but in it the vesicles, though

of small size, are few in number, perfectly distinct and separated from each other, and drying up in a few days, disappear without any serous exudation or local irritation.

Eczema impetiginodes, as its name indicates, very closely resembles impetigo; in both there is a purulent discharge, but the crusts or scabs which form on the affected part are always of a greenish hue, and the discharge purulent in the latter; while they are yellowish, or yellowish-brown, and the discharge sero-purulent, in the former. The chronic forms of the disease are liable to be mistaken for chronic lichen, especially for lichen agrius, when seated on the hands, a serous exudation being then usually present, but the latter eruption never loses its papular character, the portion of the integuments which is affected being raised unevenly, rough, and not marked by the cracks and fissures so characteristic of chronic eczema; and the serous exudation is small in quantity, is evidently caused by the local irritation to which the eruption gives rise, and only occurs occasionally. With psoriasis, too, chronic eczema may be confounded, by the superficial observer, in consequence of the epidermic desquamation by which it is attended, but the formation of true scabs never takes place in the latter, nor the copious serous exudation in the former. The diagnostic marks between impetigo and eczema have been noticed when describing that eruption. Eczema faciei is distinguished from herpes, in addition to the difference in the character of the eruption already mentioned, by the latter affecting the mouth or lips alone, while the former is not confined to any special locality.

Eczema capitis may be confounded with impetigo or herpes of the scalp; it is diagnosed from either by the copious serous exudation, which dries rapidly into yellowish, not greenish, crusts, by the rapid and excessive formation of soft furfuraceous scales, and by the hair not being affected. For porrigo capitis it can scarcely be mistaken, but the characteristic differences between the two eruptions will be more easily understood by deferring the mention of them until describing that disease." (p. 80.)

This extract will at once exhibit the style of the author, and the care that he has taken to render an accurate diagnosis easy. But we should be doing him great injustice did we not point out the eminently practical character of the work. As regards treatment, not only is the treatment of each disease elaborately detailed when treating of it, with all the modern improvements and additions to our remedial means, but he has added a most valuable chapter on the therapeutics of diseases of the skin, in which he gives a *resumé* of all the means at our command, enriched by extensive reading and his own personal experience. Our limits do not permit us to enter into a fuller analysis of the volume, but we strongly recommend it to our readers. It is less bulky, cheaper, and contains all that is valuable of the larger modern treatises, and we need not add that it contains much important matter not dreamt of by the older writers.

We repeat, that it is throughout essentially a practical treatise—practical in its descriptions, in its diagnosis, and in its treatment. It bears the marks of great care, and of extensive observation, and its style is simple, clear, and condensed. We anticipate for it a success equal, if not superior, to Dr. Neligan's former work, and for this it has our sincere good wishes.

**LIGATURE OF THE ABDOMINAL AORTA.**—This unwarrantable operation has been lately performed by a Portuguese surgeon, who has published the particulars of the case in the *Revue Medico-Chirurgicale* for March, 1852. The disease for which it was undertaken was supposed to be aneurism of the common iliac; the result, as may be readily imagined, was death. A post-mortem examination showed that the tumour was, in reality, an aneurism of the external iliac, and that ligature of the upper part of that vessel might have been accomplished.—*Prov. Jour.*

#### ADDRESS AND PRESENTATION OF PLATE TO DR. WILLIAM MCGEE OF BELFAST.

On the 14th inst., a number of the friends of Dr. McGee met in Belfast for the purpose of presenting that gentleman with an address and a piece of plate, as a testimony of the respect and esteem in which they regard his exertions in his profession, and his character as a gentleman. Dr. R. Bryce occupied the chair on the occasion, and Dr. Dill the vice-chair. A handsome collation was provided on the occasion, Drs. Patterson and Pirrie acting as stewards. There were present a large proportion of the medical practitioners of Belfast and its vicinity, and among the guests were the medical officers of the regiment at present in garrison here.

The usual loyal and routine toasts having been drank, "The health of Dr. McGee" was given from the chair.

Dr. McGEE, after reading his reply to the address, spoke as follows:—Mr. Chairman and gentlemen, I feel this to be a proud moment of my life, and my heart would be cold; indeed, if insensible to the honours conferred on me. The approval of a body of men such as I now see around me is well worth striving for, but I dare not flatter myself that your praise has been fully merited; for I am very sensible of my short-comings on many occasions. If I have been of service in warding the just claims of our juniors, or have in any way promoted their interests, I feel proud to be ranked as a worker in the field in which Dr. Samuel S. Thomson so long and so untriflingly laboured (hear). He lived to see, after many struggles, the principle admitted of remuneration for medical attendance on the poor. Who can tell if any of us shall live to see the question settled, by the awarding, not only to the medical officers of dispensaries, but to those of hospitals and other public institutions, adequate remuneration for their services. More we should not seek; with less we should not be satisfied. Each of us should so exert himself, and so use his opportunities, as though success depended on his individual efforts. If thus sought for, success must follow (applause.) That our profession is eminently entitled to the respect and gratitude of the community must be admitted. Let it not be said, for no man can with truth say, that ours is a mercenary profession. Let the public look around, and then tell what men or what class of men have so freely, so cheerfully given their time and their purse, alas! too often but scantily supplied, and have perilled health and life itself in what is called the service of the poor, but what is, truly, the service of the rich. When death comes knocking to the poor man's cabin, it is but a short step to the palace of the peer. It seems to have been forgotten that doctors require food and raiment like other people; indeed, the public so long found their calls for gratuitous service freely responded to, that they, at length, viewed your time and your services as public property, to which they had acquired a title by prescription, and they deemed the even mooted the question of remuneration to be an encroachment on their vested rights. As it is an honourable, so also is it an arduous, profession—a profession in which the prizes are few and the risks many. This will be manifest if it be remembered how very busy death has been among us. We see our friends and brothers taken from around us, and yet do not the less expose ourselves to the risk of contagion. During the last few years, many of our brethren have been summoned away; some in the fulness of time, others just entering on their career. The severing of such links are sad breakings from the chain of our friendships. This evening, again, we cannot but note and lament the absence from our board of two of our most esteemed and valued members—men who might reasonably have hoped for many years continuance here on earth; but it was ordered otherwise, and they, too, are gone. It may be said that such topics should not be introduced on festive occasions; but, surely, we can spare a minute from our rejoicing to show that our brothers, now no more, are not forgotten—that "their memories still live though their spirits are fled." I request permission to give "The memory of our departed brethren."

The toast was drunk in solemn silence, and the company shortly after separated.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JUNE 23, 1852.

We know not how it may be elsewhere, but in Ireland, at all events, there seems to be a tacit understanding that the prime object of all public institutions is the advancement of persons holding office in them, and the distribution of pecuniary benefits amongst those connected with them. And yet, again, perhaps we do know how it is elsewhere; for, to say the truth, the same laudable principle seems to prevail pretty generally. It is true that in England the practical application of the assumption is conducted more decorously, and in Scotland more cannily than in Ireland; but in one way or another it is allowed to operate. Even the Frenchman will say *c'est vrai*, and admit with a shrug that *c'est partout comme chez nous*: and so perhaps of all the world. And wherefore should it not, for such is the bent of the human mind? That self-preservation is the first law of Nature, has passed into a proverb; and what is turning circumstances to account but self-preservation. In fact, the sooner men come to comprehend this the better, and the sooner they act in conformity with such conviction the better still; but not as some men act, sacrificing the institution to selfishness or cupidity, and killing the goose with the golden eggs; or yet, again, consulting their own interests, regardless of all others. Far better to have this "understanding" clearly recognized and openly adopted, than as now, repudiated, while covertly tolerated. Restricting our observations to institutions belonging to or connected with our profession, such as Colleges, Schools, Hospitals, Societies, or Academies, we would suggest that, so far from rejecting the notion that the officers or members of them should have no personal interest in their welfare, the very reverse should be admitted. Every member of a public body should be taught to feel that, be his position in it what it may, he, sooner or later, in a greater or less degree, will be benefited by his connexion with it, and all he has in addition to learn will be, that he is not to seek to be prematurely or disproportionately benefited by it to the injury of its character or the interruption of its operations. This moderate estimate of a man's interest in the progress of an institution is not, however, the one universally adopted: as we have above hinted, a much more exaggerated one is often formed. Many, with great composure, assume that the prime object to be achieved is personal aggrandizement, the second being the success of the establishment; while some go even further, and assume that personal interests are to be consulted regardless of all other considerations. One says, I must first take care of myself and then of the College; the other, I must take care of myself, and as for the College, let it take care of itself. Nay, some will go so far as to avow a determination to turn circumstances to account, like the Irish patriot at the Union, who, when asked whether he, too, was about to sell his country, candidly replied "that he was, and right glad to have a country to sell." Beyond this extreme others blush not to go: as where one entrusted with the care of an institution deliberately conspires with others equally bound to uphold it, to defeat its objects. In fact, in one shape or another, the principle to which we allude prevails, and all that is wanted is a check to prevent its mischievous application.

Each man has his own way of discharging his functions, from the exercise of the elective franchise to presiding over the executive government; and each should, if possible, be bound to act, if not with integrity, at least with decency. But here is the difficulty. How are men to be brought to act disinterestedly, honestly, and wisely, even when motives are not pressing. In the exercise of the elective franchise in institutions to which such a share in their government has been conceded, we see men every day displaying a total disregard of the trust reposed in them; while at the same time we see others still more bound to act with firmness equally negligent. The consequence is, that selfish men achieve their objects with impunity, and that all who have to discharge the duties which are thus betrayed are suspected of similar delinquencies. Hence the universal belief that conductors of public institutions undertake their offices with a view to some pecuniary advantage; or, as it is in bitterness said, with a view to what is called jobbing: yet if men would think for a moment, they must see that such practices cannot be very general, seeing the impossibility of rendering them effectual. Indeed this rather stale cry, often raised against individuals, becomes every day less potent, in consequence of its misapplication, the real "jobber" seldom being the object of it, and the cry being often raised for the purpose of diverting attention, as the flying pickpocket cries stop thief to baffle his pursuers. We do not mean to say that no "jobbing" or perversion of public objects to private ends prevails; what we aim at is to remove an impression that such is general. We know well that where no popular element enters into the composition of a public body, and no publicity operates as a check on its proceedings, great abuses necessarily are tolerated, but where representation and freedom of approach exist it is otherwise. An institution governed by a few easy and unsuspecting men at the mercy of a knot of greedy, needy, and unscrupulous placeholders is, perhaps of all others, the most liable to the consequences at which we have been glancing.

## SURGICAL COLLEGES.

WHILE the Universities and Medical Colleges fall back on the legislation of a barbarous period to sustain them, the Colleges of Surgeons adjust their regulations to the progress of society. The following are the Bye-laws of the College of Surgeons of England, made in conformity with a charter lately obtained, in addition to one not ten years old. The provisions of these laws do not much affect the Surgeons of Ireland, but we publish them to remind our readers that they must keep pace with such changes:—

*Bye-laws of the Royal College of Surgeons of England, relating to the Election and Admission of Members of Council.*

1. The place and time appointed for every meeting of the fellows for the election of members or a member of the council shall be announced in the *London Gazette*, and in two London daily newspapers, not less than thirty days, and not more than forty, before the day of meeting.

2. Every fellow desirous of a seat in the council shall, within ten days from the publication of the *London Gazette* in which the day of meeting for the election shall be announced, transmit or deliver to the secretary of the college or person acting for him, a notice and declaration signed by himself in the following terms:—

"I, A B of C, Fellow of the Royal College of Surgeons of England, do hereby declare that I am a candidate for a seat in the council of the said college; that I am in the *bona fide* practice of the profession of a surgeon, and that I do not practise as an apothecary."

Together with a nomination signed by six fellows of the college in the following terms—viz.,

"We, the undersigned Fellows of the Royal College of

Surgeons of England, do hereby certify that *A B* of *C*, is, in our estimation, a fit and proper person to be a member of the council of the said college; and we do hereby nominate him a candidate for a seat in the said council."

And also a certificate, signed by three fellows, in the following terms—viz.,

"We, the undersigned Fellows of the Royal College of Surgeons of England, do hereby certify, on our own personal knowledge, that *A B* of *C*, is in the *bona fide* practice of the profession of a surgeon, and that he does not practise as an apothecary."

3. The names of the eligible fellows (who shall have been nominated as candidates for the council in the manner required, and who shall have complied with the provisions and conditions respecting the said notice and declaration, nomination, and certificate), together with the names of the six fellows by whom they shall respectively have been nominated, shall be published in the *London Gazette* and in two London daily newspapers not less than ten days before the day appointed for the election.

4. Members of the council retiring from office by rotation and desirous of re-election, shall intimate such their desire in writing, addressed to the secretary or person acting for him, within ten days from the publication of the *London Gazette* in which the day of meeting for the election shall be announced; and the names of such members shall be published in the *London Gazette* and in two London daily newspapers, at the head of the list of the names of the several other candidates to be published as aforesaid.

5. At every meeting for election into the council, not less than fifteen fellows being present, the chairman having declared the business of the day, the secretary or person acting for him shall proceed to announce to the meeting the names of the several candidates so published as aforesaid, in the order in which such names were so published, except the names of such of the said candidates as shall previously have signified to the secretary in writing, his or their desire not to proceed to the election; whereupon a ballot shall be forthwith taken for the election of such number of members as shall be required to fill up the vacancies in the council; and such ballot shall be kept open for three hours, unless for the space of ten minutes after notice from the chairman of his intention to close such ballot, no fellow shall actually ballot, in which case the chairman shall declare such ballot to be closed, although the three hours may not have expired; and at the expiration of such three hours, or upon such previous closing of the ballot, as the case may be, the balloting-box shall be opened by the chairman, who shall ascertain the result of such ballot, and shall forthwith declare the names of the fellows elected into such vacancies, and thereupon the election of such fellows to be members of the council shall be deemed complete. But if, after the result of such ballot shall have been so ascertained, and the names of the fellows elected shall have been declared, it shall appear that the number of fellows so elected shall from any cause not be sufficient to fill up all the vacancies, the proceedings of the meeting shall be continued, and the ballot taken again until all the said vacancies shall have been filled up by the election of sufficient fellows for that purpose.

6. When there shall be any vacancy in the council by the death or resignation of an elective member, the fellow of those elected who shall have been so elected by the smallest number of votes, shall be the substitute member of council in the room of such elective member; and when more than one such vacancy shall be required to be so filled up, the fellow elected by the smallest number of votes shall be the substitute in the room of that member whose period of office would have first terminated, and so in regard to each of such vacancies respectively. And if it shall at any time happen that more than one member shall be elected by the same number of votes, being with reference to the other fellows elected the smallest number of votes, the youngest in standing as a fellow of the persons so elected by such equal number of votes shall be the substitute member; and so in regard to each of such vacancies respectively.

7. Every member of the council shall, prior to his admission, subscribe his name to a copy of the bye-laws, in testimony of having engaged himself to the observance thereof; and upon his refusal or neglect so to do, within the period of three months from the date of his election, his election shall be void.

8. Every member of the council shall, prior to his admission, pay twenty guineas; but which sum shall be paid on his first admission only.

## CASE OF POISONING BY SULPHURIC ACID.

By Dr. J. SEWELL, Physician to the Hôtel Dieu, Quebec.

A SAD case, possessing more than usual interest, both from the poison selected and the quantity swallowed, having recently occurred in my practice, I think it my duty to submit its history to the profession.

Mrs. E., aged 23, the mother of two children, had about three weeks since suffered a miscarriage, which left her feeble and nervous. In this state, more easily acted upon by depressing causes, she heard a sermon, the effects of which on her mind (according to her own statement to me) she could not throw off; she fancied herself without the pale of salvation—her soul condemned and lost; in fact, she became insane with this predominant idea. In this state she remained, with some shades of variation, until the 16th of February last; her husband had been repeatedly warned that she would probably attempt to commit suicide, and he fortunately arrived in time to prevent her committing it by suspension a few days previous to the fatal accomplishment of her purpose. Her husband's business led him to the employment of tincture of bromine, iodine, and other poisonous materials; these he had carefully disposed of beyond her reach. A day or two before the sad affair, he bought at a druggist's one pound by weight of concentrated sulphuric acid, which shows about five fluid drachms to the ounce; he poured the whole of this into two large tumblers, dividing the quantity equally to form what these artists call a "battery," by which they galvanize the silvered plates previous to submitting them to the vapour of iodine in the production of daguerreotype likenesses. He had placed, as I have said, the bromine and iodine, &c., under lock, but never suspecting the probability of her using this powerful acid for the purpose of self-destruction, he took no precaution with it. She was absent from her usual sitting apartment about three p.m. of the 16th of February, for somewhat less than two minutes, but she had time to effect her purpose, as she told him on returning to the room. On instant examination, he found that she had emptied one of the tumblers of its contents, except about half a fluid ounce, and the already excoriated state of her mouth and chin fearfully corroborated her story.

Assistance was quickly sought, and, on my arrival, finding that the stomach-pump had been imperfectly used, I reintroduced it. At this time about forty minutes had elapsed since the acid had been swallowed. I found her pale, and perfectly collapsed, cold skin, no pulse at the wrists, and the action of the heart feeble and indistinct. The first effect of the poison had been to prostrate all the powers of life nearly to extinction. Milk and oil were first injected into the stomach and quickly withdrawn, but the appearance presented destroyed all hope; it was dark, grumous-looking blood, mixed with a shred-like filamentous substance. Oil, chalk, and carbonate of magnesia were freely used, with a view to neutralize the acid or blunt its action. Some reaction came on in about an hour, when her sufferings became dreadful to witness; she could scarcely be held in bed, her mind had cleared at once, and she "wondered what could have made her do it," and then she was "burning alive," were expressions incessantly uttered. She could, and did, swallow everything that was offered to her, till delirium and coma closed the scene.

The body was carefully examined the next day, about twenty hours after death, and it is quite a hopeless task to give an adequate idea, by any description, of what we saw. The whole of the forepart of the stomach, that is, its greater curvature, was destroyed, and fluid of the same appearance as that drawn up by the first action of the stomach-pump, was on the surface of the intestines, and welled up from amongst their convolutions. The omentum was to a great extent in shreds, the back part of the stomach was likewise injured, and looked charred, but in a less degree; the food (and she had dined heartily at noon) was pushed towards, and lay at and near the pylorus. I apprehend that the mass of food prevented the immediate contact of

the acid, and thus accounted for its different state of disorganization; the great arch of the colon, where in contact with the stomach and omentum, was in some trifling degree affected. The stomach was literally dissolved in sulphuric acid; one or two drops from the scalpel fell upon some linen, and a hole through which the finger could be thrust was quickly made, showing how active this powerful acid still was. Doubtless, the acid had continued to destroy the texture of all parts it came in contact with even after death, but much of the disorganization that we witnessed had been effected by this destructive agent in the three hours that intervened between the time of her swallowing it (three to six p.m.) and the hour she died.

It is pretty evident that no plan of treatment could have been adopted in this sad case with any chance of success, either with a view to withdraw the acid before it had time to work irreparable injury or to neutralize it. There was a well marked excoriation at each angle of the mouth and beneath the chin, much more apparent after death; the inside of the mouth and lips were of a dead white, as if burned by a hot iron. It would have been interesting to have examined the fauces, œsophagus, &c., but it could not be done.—*Canada Med. Jour.*

### INJURIOUS EFFECTS OF TARTAR EMETIC.

By Dr. BOLING.

THESE are thus described:—The patient may be seen to be doing very well under the antimony, the dulness on percussion and rapidity of pulse diminishing, the skin moistening, and the respiration improving; when suddenly in some cases, more gradually in others, he becomes restless, thirsty, and somewhat purged, the belly becoming tympanitic, and sometimes tender. He vomits, or tries to do so; the tongue is dry and pointed; jactitation and anxiety of countenance appear, together with delirium, and perhaps shortly before death, stupor. Occasionally jaundice supervenes; and in a few cases the matter ejected closely resembles that of yellow fever. During these occurrences the pulse becomes frequent, hard, small, and thready. Death may take place within six hours after the first appearance of these unfavourable symptoms, more frequently it is delayed for ten or twelve hours, and in some cases yet longer.

Simultaneously with the advent of the above symptoms, or just preceding them, there is a more or less rapid disappearance of the symptoms of the original disease. A lung which seemed almost completely solidified, in four or five hours becomes permeable, and yields a healthy respiratory murmur, all the symptoms of the pneumonia undergoing a similar improvement. The violence and rapidity of the abdominal disease are in direct ratio to the suddenness of the improvement in the disease of the lung. In any case of pneumonia treated by antimony, the supervention of the least tympanitis, thirst, and diarrhœa, must be looked upon with suspicion, as the probable precursor of this serious condition; and Dr. Boling regards the patient's doom as almost decided, when, in addition to these symptoms, there is a *rapid*, in place of a *gradual*, diminution of dulness on percussion, *unattended with the crepitant râle of resolution*. The observance of this peculiarity in the physical signs has enabled him to announce portending mischief in patients apparently convalescent.

This cannot be a rare occurrence in the Southern States of America, as the author has seen almost as many die of the induced as of the primary disease. He suspects that some of the cases described as loss of tolerance of antimony by the Italian practitioners, are of this nature, although, if so, their delineation is very incomplete. Göllis gives a graphic account of a similar train of phenomena produced by large doses of calomel in hydrocephalus and cramp.

Dr. Boling is disposed to attribute this effect of antimony to its direct action on the intestinal canal, by reason of a portion of the quantity administered not becoming absorbed; and believes that our object, in attempting its prevention, should be, to administer the drug in such divided doses as to secure its complete absorption. Although not in the habit

of giving large doses, he has diminished these; and finds the remedy just as efficacious now that he gives only from three to six grains in the twenty-four hours, as when he gave double the quantity, while the mischievous effects have been of much less frequent occurrence. He dissolves the above quantity in six ounces of water, and gives a teaspoonful every half hour in the day, and two teaspoonfuls every hour at night. He prefers water as a vehicle, as mucilaginous fluids delay the absorption of the medicine.—*Amer. Jour. of Med. Sci.*

### LARGE INFANTS.

IN a recent paper in the *Zeitschrift für Geburtsh.*, Dr. Siebold observes that when new-born infants are not actually weighed, the most ridiculous exaggerations prevail in respect to the estimates of the weight of the larger ones. Since 1825, he has had all the children weighed at the Berlin, Marburg, and Gottingen Institutions, with which he has been successively connected, and the heaviest he has met with only reached 11½ pounds, notwithstanding we peruse fabulous statements of 20 pounds being attained. That such statements, however, are not always fabulous, is seen from the fact of a recent instance recorded in an American journal by Dr. Johnston, in which the child weighed exactly 20 pounds, and the placenta 3 pounds. Its length was 25¼ inches, the breadth of the shoulders 8½, and of the hips 7¾ inches. The occipito-mental diameter was 6¾ inches; the occipito-frontal 5¾, and the biparietal 4¾ inches. The labour was accomplished in eight hours, but owing to the great delay which the passage of the shoulders and hips entailed, the child was still-born. In another case, recently observed by M. Depaul, the child, which was born dead with the epidermis detached, after version, weighed nearly 14½ pounds, and measured about 21 inches.—*American Jour. of Med. Science.*

A LONG FAST.—On the 29th of April, a negro woman belonging to Mr. J. Harpending of this county, got lost in the woods. Mr. H. thinking she had been stolen offered a reward for her. He heard nothing of her until the 11th of May, when some boys who were hunting found her apparently dead. They returned home, and informed some gentlemen of the fact. The Messrs. Harpending, George, and one or two others, went in search of, and found her almost covered with snow; and supposing, as a matter of course, that she was dead, one of the party started to get a slide, while the others struck up a fire and awaited his return. One of them, wishing to see if decomposition had taken place, touched her with his cane, when to his astonishment, she slightly moved her head. After applying the usual remedies she recovered sufficiently to converse with them. She stated that she had not eaten or drank anything but snow since she left home, and had been out in the weather all the time—fourteen days.—*Phil. Medical Examiner.*

ETHERIZATION IN PARTURITION NINETEEN YEARS AGO. Dr. W. Channing reports in the *Boston Medical and Surgical Journal* for March 10, 1852, the following interesting details on this point:—Dr. Channing was recently attending a case, in which he administered ether with "excellent effects." In his visit following the delivery, he asked his patient "how many times she had used ether?" She named them, and added "that there was one other time in which she used it with great advantage." I asked when. "Nineteen years ago, she said, she gave birth to her eldest son. Her labour lasted more than a fortnight. In the absence of her physician, her husband tried to find something which had given some relief in her former and first labour. He failed; but being engaged in preparing a chemical lecture, and making experiments with sulphuric ether, he thought he would try that. It was wiped freely over her face, and forehead, and *breathed*. To his surprise all her distress passed away—the spasmodic twitchings disappeared—violent voluntary effort, which constituted so much of her misery then, and has in all subsequent labours, ceased to annoy her. Her physician arrived, and was so much pleased with the effects of the ether that it was employed during the rest of the labour. Her labour was now easy, was soon completed, and a stout living boy born." Such was her account of her first use of sulphuric ether to diminish or to abolish pain.—*Med. Ex.*

## EFFECTS OF EASTERLY WINDS.

In reply to a letter on this subject, perhaps you will permit me to say that we have very strong reasons for believing that the distressing influence of the east wind depends upon its peculiar electrical condition. That its effects are produced by the abstraction from the body of a large amount of vital force, in the state of electricity, seems highly probable. In confirmation of this view, I may mention that some years ago, when the gigantic hydro-electric machine was first exhibited at the Royal Polytechnic Institution, the men whose duty it was to assist in the peculiar department to which it belonged, were almost constantly complaining of rheumatic pains, and of affections of the mucous membranes of the nose, &c., such as we frequently notice among invalids who are sensitive to the influence of an east wind. Suspecting from preliminary inquiries that the cause was the abstraction of electric force by the enormous boiler-machine, I was induced to watch the cases more carefully, and thus was enabled to determine satisfactorily that at those seasons when the apparatus was exhibited daily, the symptoms were persistent; that when it was exhibited merely on alternate days, they were intermittent; and that when weeks or months elapsed without any experiment, the distressing effects upon the body and mind entirely disappeared, but only to be again renewed with the revival of the cause. I may be allowed to remind you that the great peculiarity of the hydro-electric machine is its negative condition. The steam, in its rapid escape, abstracts so much electricity that the mass of insulated metal, in obedience to a natural law, seeks to recover its equilibrium by robbing surrounding bodies of their electric force; and hence the loss of vital power. So rapid, also, have its effects sometimes been, that I have known invalid visitors suffer severely after having been in the room only a few minutes. I may mention, in conclusion, that the unpleasant effects to which I have referred were perceptible during the working of the machine, whatever might have been the condition of the external atmosphere.—*Letter in Lancet.*

**A SIMPLE REMEDY FOR ASTHMA.**—Take a strongly saturated solution of nitrate of potash; soak amadou in this and dry it. Get a flask with a large opening, the cork of which is pierced in the centre to give a passage for a tube. Light the piece of amadou and put it into the flask, and then cause the patient to inhale, either by the mouth or nostrils, the gas which is disengaged. At the end of some inspirations, he experiences a relief which continually increases. Such is the very simple proceeding which I have made use of with such success this some time back when consulted by patients affected with asthma. To give a satisfactory explanation of this method of treatment, would perhaps be rather difficult. I will confine myself to the following opinion, still in a doubtful way. May not a small portion of oxygen, disengaged by the nitrate of potash, be inspired by the patient; for we know that in asthmatic patients the sanguineous circulation in the lungs is incomplete, that the blood is only imperfectly oxydized—it is black—the excess of carbon in it is not consumed. Is this excess of carbon consumed by the oxygen absorbed?—*M. Farrot in Revue Méd. de Paris.*

## COUNTY DUBLIN MEDICAL ASSOCIATION

In furtherance of the valuable suggestions of Doctors Kingsley, Morrison, and Waters, that County Medical Associations should be formed throughout Ireland for the purpose of advancing and protecting the interests of the Medical Profession, a Meeting will be held at FANNIN'S, 41, Grafton-street, on Friday, the 25th of June, 1852, at the hour of Three o'Clock p.m., for the purpose of appointing a Chairman, Treasurer, and Secretary, &c.

JAMES T. MAGUIRE, M.D., Secretary pro tem.

Palmerston, June 21, 1852.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries,** 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

## THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BREEDING, CUPPING, THE APPLICATION OF LEECHES, &amp;c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

### SURGICAL SOCIETY OF IRELAND.—MAY 1.

Mr. TRANT, President of the College, in the chair.

ON THE OIL OF THE *GADUS CARBONARIUS*,  
OR BLACK POLLACK.

By Dr. BAGOT.

ON a former occasion I had the pleasure to bring before the Surgical Society of Ireland the subject of cheap Newfoundland cod-liver oil, and strongly advocated its use as a medicinal agent. Since that time I have had no reason to change the opinion I then entertained as to the benefit likely to be derived from its administration; but as I was then unable to point out the manner in which a sufficiently large supply might be procured, and as the medicine vendors refused to coöperate with those who were anxious for its importation, I regret it has never come into general consumption, and the great majority of the population of this country is excluded the use of a medicinal agent of the highest importance, from want of means to procure an article which, if genuine, carries a very high price in the market. Some months since, William Sinclair, Esq., of Drumbeg, Mountcharles, county Donegal (a gentleman with whom I have not the pleasure to be acquainted), transmitted to me a small quantity of the oil of the *gadus carbonarius*, or *black pollack*, to be exhibited at one of the evening scientific meetings of the Royal Dublin Society, and being struck with its resemblance to the oil of the *gadus morrhue* or common cod, I administered the sample to a patient in phthisis, with whom it agreed remarkably well, and wrote to Mr. Sinclair to the effect, that I believed the oil to be almost identical with that procured from the cod, and might probably be exhibited as a medicine with the same results. In answer, he said he would have much pleasure in sending me a larger quantity for medicinal purposes if I wished to test its efficacy, which offer I at once accepted, announcing to him that I would bring the matter before the profession, if there were sufficient grounds for so doing in the experiment I was about to make. The oil not having reached me as soon as I had expected, I have

not given it so extended a trial as is desirable, and from other unavoidable circumstances, I have been unable until within the last ten days to have it tried by other medical men, whose testimony in its favour would have been of the greatest importance; yet having administered it to some patients in phthisis, and found my hopes fully realised, I was anxious to bring the subject before this Society, and through this Society to the profession at large, before the termination of the session, preferring even an imperfect communication of imperfectly ascertained results, to allowing so important a matter to lie another year in abeyance; and the more so, as the fishing season is at hand, and I hoped that even this notice of the oil might induce some of the profession connected with hospitals and dispensaries to enter into correspondence with the manufacturer, procure some of the oil, and try it for their own satisfaction. By comparing the sample of pure cod-liver oil from Austin's Medical Hall in Camden-street, with that of the black pollack, which I now submit, the Society will perceive it is impossible to distinguish one from the other by the appearance, taste, or odour, although the latter has been prepared in the roughest manner, and I believe not cold-drawn, and both yield the same pink colour with sulphuric acid. Mr. Sinclair informed me that he could this year supply as many as 500 gallons of the oil of the black pollack, if they were required, and could sell it at a remunerative profit for 5s. per gallon, and I trust it will yet prove the means of lowering the present exorbitant price of cod-liver oil, and of introducing this valuable remedy to the thousands at present precluded its use; and I would suggest that any gentleman who may be led to its administration should publish the result in the columns of the *MEDICAL PRESS*, which are ever open to any communication that may advance professional science or benefit the public.

Within the last fortnight, Dr. Benson, at my request, has, in the kindest manner, been trying the oil in the City of Dublin Hospital, though I regret I was unable to send him more than a small quantity for that purpose, and I trust he will mention to the Society the results, as far as they can be gleaned, though I know that experiments of

this kind must be carried out on a large scale before we can arrive at satisfactory conclusions. I believe we are as yet in our infancy with regard to the number of those oils which may be used with advantage, and the administration of even the cod-liver oil requires more attention than is generally supposed, and its effects should be closely watched by the physician, who should give it in small doses, with occasional intermissions, to prevent that derangement of the digestive functions which so frequently follows its exhibition. In conclusion, I may remark, that some intelligent patients of mine said that the oil of the *gadus carbonarius* was less disagreeable to the stomach than some of the oils procured at the best establishments in Dublin; and a young medical friend of mine who had tried it with two patients, had heard from them the same observation.

Dr. BENSON said, that so far as he had had an opportunity of testing the medicinal value of this oil, he could speak favourably of it. Having received a quart of it from Dr. Bagot, he selected three of the most intelligent of his patients who were then using the cod-liver oil, and gave them this new oil instead, directing them to take it at the same times and in the same quantity as the other. These all expressed themselves well pleased with it. They scarcely perceived any difference either in its immediate effects on the stomach, or on the progress of their diseases, which were different forms of phthisis pulmonalis. Dr. Benson said that of course this quantity was too little to enable him to speak decidedly about it. It ought to be tried with a greater number of patients, and for a much longer time than this lasted. But when he gave to the same patients, by way of experiment, similar doses of sweet oil and very nice linseed oil, their stomachs soon rebelled, and their progressive improvement was checked. Good trotter oil, however, was borne by the stomach pretty well, though not quite so easily as the oil now presented. He therefore considered that Dr. Bagot deserved well of the profession and the public in introducing this oil to the notice of the Society.

Dr. JACOB observed, that there was no reason in the world why this species of cod might not afford the oil of the requisite quality as well as any other; indeed, the probability was that many, if not all, oils obtained from the livers of fish, possessed medicinal qualities. Even the sun-fish oil, as it is called in commerce, obtained from the liver of the basking shark, might be valuable in this respect. Dr. Bagot's announcement he considered very important and well deserving of attention.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ON THE PROTECTION AGAINST SMALL-POX AFFORDED BY VACCINATION, ILLUSTRATED BY THE RETURNS OF THE ARMY, NAVY, AND THE ROYAL MILITARY ASYLUM.

By T. G. BALFOUR, M.D.,  
Surgeon to the Royal Military Asylum.

ONE of the principal difficulties in the investigation of this subject, the author thought, arose from the impossibility of ascertaining what proportion of the general population was unprotected by vaccination. Accurate deductions could, however, be founded on the returns of the army, navy, and Royal Military Asylum. Although the returns of the first department did not show the actual number of soldiers who had been vaccinated or had the small-pox, yet a tolerably accurate approximation might be obtained. From returns forwarded to the Army Medical Board, it appeared that out of 90,092 recruits medically inspected and found fit for service, 20,132 bore marks of small-pox, 64,096 had marks of vaccination, and 5864 bore no distinct traces of either. By the rules of the service, the latter would be immediately vaccinated; added to the second class, a total of 69,960, or 78 per cent. of the whole, would be protected by vaccination; 22 per cent. representing the proportion of those protected by previous small-pox. The question next arising was, what number of admissions into hospital and deaths by small-pox had occurred in this num-

ber? Abstract No. 1 in the Appendix furnished this information, and it showed the proportion of cases of small-pox to have been 66, and the deaths 8, in every 100,000 men serving throughout the army. But the prevalence and mortality varied in different portions of the force. Thus the deaths had been four times as numerous among the troops in the united kingdom as in temperate colonies, and eight times as numerous as in tropical colonies; while a still greater disproportion was found to exist in the admissions into hospital. A comparative statement of the proportion of small-pox among the black troops and Europeans serving in tropical colonies during several epidemics, was furnished, by which it appeared that the disease literally decimated the black troops, while not a single death occurred among the European soldiers serving in the same garrisons. The author observed, that if the hypothesis be correct, that the protective power of vaccination became gradually weaker, and at length died out, the mortality from small-pox should be greatest among the old soldiers. The following return illustrated this point:—

Ages.	Aggregate strength at each age.	Died by small-pox.	Ratio of deaths per 1000 of strength.
Under 20 .....	43,833	15	0.342
20 to 25 ..	90,041	28	0.311
25 to 30 .....	49,285	3	0.061
30 to 35 .....	37,151	8	0.216
35 to 40 .....	25,017	1	0.040
40 and upwards...	9,270	0	...
Not known.....	...	1	...
	254,957	56	220.0

Returns from the navy exhibited the same satisfactory evidence of the protective power of vaccination. The vaccination register of the Royal Military Asylum had been kept with great care, and reliable evidence could be obtained from it. During a period of forty-eight years, 31,705 represented the aggregate strength of the boys, and among these only 39 cases of small-pox occurred, of whom 4 died. It must be borne in mind that every child bore marks of cow-pox or small-pox, or had been subsequently vaccinated; so that, in a population completely protected, the average was but 123 cases, and the deaths but 12, in every 100,000, being a still lower ratio than in the army serving in the united kingdom. Another return displayed the comparative amount of protection afforded by vaccination and previous small-pox. The ratio of cases per 1000 of the latter was 6.15, and the deaths 2.05; while of those previously vaccinated, the ratio of cases was 7.06, and the deaths 0. All the deaths were thus from secondary small-pox. The author thought the preceding facts afforded most conclusive evidence of the protective value of vaccination, while the extensive numbers, and the period of time over which the observations extended, justified a very firm reliance on such evidence. He thought this evidence had an important bearing on the proposition recently made to legalize inoculation. While so large a proportion of the community remained unprotected by vaccination, he thought such a course most unjustifiable. Absolute immunity from small-pox was not to be expected, but the foregoing returns showed the great exemption obtained by vaccination. Vaccination should be made compulsory. It had been said that this would interfere too much with the liberty of the subject; but so to a certain extent did all measures relating to the public health. The prejudices of the few must be made to give way before the interests and safety of the many. In factory acts, parliament recognized the principle of protecting the young against an amount of labour calculated to be injurious, and this in spite, not of the prejudices, but of the so-called rights of parents; and it would be but an extension of this humane principle to make vaccination compulsory, and thus afford protection against a malady of so fatal a character as small-pox.

ON THE DIMINUTION OF THE CHLORIDES IN THE URINE, OR THEIR ABSENCE FROM THAT FLUID, IN CASES OF PNEUMONIA; AND ON THE CHEMICAL COMPOSITION OF THE SPUTA IN THAT DISEASE.

By L. S. BEALE, M.B. Lond.

The author's attention had been first drawn to this subject by some observations of Dr. Redtenbacher, who had noticed the absence of chloride of sodium from the urine in pneumonia, and who, in 1850, had published the fact that the chloride gradually diminished until the period of hepatization had occurred, when it disappeared altogether from the urine, and gradually reappeared as resolution progressed. A diminution of the quantity of chloride in a variety of diseases of the inflammatory type had been noticed by Franz Simon; but in these diseases they appeared only to suffer diminution, and not to be invariably absent from this fluid, at the period of inflammatory condensation, as Dr. Redtenbacher had shown to be the condition in pneumonia. The author, with a view, if possible, of making out the channel through which the chloride of sodium was eliminated from the system in this disease, or of determining the locality in which it was stored up, and desirous also to trace the connexion between the absence of the salt from the urine and the occurrence of hepatization, had instituted the observations which formed the subject of the paper. The observations were made on cases in King's College Hospital, and were taken indiscriminately from amongst the mild and severe. The mode adopted by Dr. Redtenbacher, to estimate the quantity of chloride present, appeared to be simply approximative. The author desired to obtain quantitative results, and pursued a closer and more accurate method of analysis. He showed that if the chloride was estimated merely by nitrate of silver and nitric acid, volatile chlorides would be thrown down, as well as the fixed chloride of sodium, and he had not overlooked the fact of the presence of hydrochlorate of ammonia as one of the ordinary constituents of urine. By the rude method just mentioned, chloride of sodium might be entirely absent from the urine, and yet an abundant precipitate be furnished by nitrate of silver, insoluble in nitric acid. The following was the method pursued: The reaction and specific gravity were first observed; 1000 grains were then evaporated to dryness over a water-bath, and subsequently at 200 deg. in a water-oven, and the dry residue weighed for the amount of water. A weighed portion of the solid residue was incinerated, and carefully decarbonized at a dull-red heat; and the weighed residue, by calculation, gave the amount of salts present in 1000 parts. The soluble portion of this saline residue was taken up by distilled water, acidulated with nitric acid; nitrate of silver being then added, the presence of fixed chloride was at once detected. The precipitate, if any, was washed, dried, ignited in a porcelain crucible, and weighed, and the chloride of sodium calculated from the chloride of silver obtained. This method gave in each analysis the quantities of water, solid matter, fixed salts, and chloride of sodium, in 1000 grains of urine. A similar method was pursued in estimating the amount of chloride existing in the sputa, blood, and urine. The necessity for correct diagnosis, and the selection of well-marked cases of the particular morbid condition under consideration, was of the utmost importance in all chemico-pathological investigations. The notes of the cases which formed the subject of these analyses were kept by the clinical clerks of the physician under whose care the patient had been placed. The variable quantities of chloride of sodium, its deficiency or absence, was not peculiar to pneumonia, but might sometimes depend upon the proportion taken in with the food. It might, however, be considered that healthy urine contained 3.5 per 1000 or five per cent. of the solid matter. The absence of chloride of sodium from the urine indicated generally a deficiency, or at least no excess, of that salt in the blood; but the interesting fact in regard to pneumonia was, the total absence of this salt from the urine at a particular phase of the disease, and its excess in other secretions, or in the inflammatory product itself; and this fact

might be viewed as one of a series of phenomena, which, when more fully investigated, was calculated to shed some light on the hidden processes of pathological metamorphoses. Then followed a full record of nine cases of pneumonia, with the analysis of the urine. The sputa were analyzed in the third, seventh, and eighth cases. The hepatized portion of the lung in one fatal case was also analyzed, and the results compared with equal weights of healthy lung. The deductions which the author sought to establish were: 1. That in pneumonia there is a total absence of chloride of sodium from the urine, at or about the period of pulmonary hepatization. 2. That as resolution of the inflammation proceeds, the chloride becomes restored to the urine. 3. That at this period the serum of the blood is found to contain a greater proportion of chloride than in health. 4. That the presence of chloride of sodium in the urine indicates an excess of that salt in the blood; and that its absence from the urine implies that the blood contains less than the average quantity. 5. That the sputa of pneumonia contain a greater quantity of fixed chloride than healthy pulmonary mucus. 6. That there was reason to believe that the absence of this salt from the urine in the stage of hepatization, depended on a determination of the salt to the inflamed lung; and when that resolution occurred, it was reabsorbed, and appeared in the urine.

MEDICAL SOCIETY OF LONDON.

NEW MODE OF APPLYING MEDICAL SOLUTIONS TO THE LARYNX.

DR. THEOPHILUS THOMPSON exhibited to the Society an instrument which he is accustomed to use for the purpose of making applications to the interior of the larynx. It is a syringe having a small glass cylinder and a silver tube, slightly curved, and at its extremity expanded into a globe about a third of an inch in diameter, perforated all around with numerous very small apertures. The piston rod is surmounted with a ring, into which the thumb can be introduced, so as to work the instrument steadily. The tongue of the patient being held down with a spatula or with the finger (whether the epiglottis can be seen or not), the extremity of the tube is readily introduced, and the solution injected. The conditions of larynx in which Dr. Thompson finds most occasion for this instrument, are those which are benefited by nitrate of silver; and he usually employs about half a drachm of the solution recommended by Dr. Horace Green, containing two scruples in the ounce of water. Dr. Thompson remarked that patients and practitioners seem agreed in the impression that advantage is derived from such an application, and he considered this mode of introducing it less rough and disagreeable than the curved probang with a sponge at the extremity, as used by Dr. Green, and more precise in the direction of the fluid than the forceps, having one blade armed with a sponge, as ingeniously contrived by Dr. Cotton. Dr. Thompson was indebted for the suggestion to Dr. Boot, who mentioned to him having seen in an American newspaper the notice of a syringe employed for the same purpose by Dr. Asa Warren of Boston.

Dr. WARD said that some time ago he had contrived a syringe similar to the one exhibited by Dr. Thompson, but he had not made it public.

FOREIGN BODIES IN THE CÆCUM.

Dr. CRISP briefly referred to a case of peritonitis which terminated fatally, and which had its origin in the impaction of two little bodies in the appendix vermiformis. The patient had been in the habit of taking large quantities of soda and magnesia. He had not examined these bodies, but believed that they were composed of these materials. A pathological specimen was exhibited.

Dr. OGIER WARD exhibited what appeared to be an APOPLECTIC CLOT FROM THE BRAIN OF A BOY FOUR YEARS OF AGE,

who died on the seventh day of an attack of purpura. The child was chastised at school, but not severely, on the 14th

of May, and the purpura broke out on the 17th, in the form of red spots of various tints all over his body and limbs, and numerous ecchymoses confined to the posterior surfaces, except one on his forehead. Dr. Ogier Ward saw him only once (on the 21st of May), when he seemed in perfect health, except the presence of the eruption, and he remained so till the morning of the 24th, at four a.m., when he got up to the night-chair, but passed nothing. At nine a.m., he complained of his head, and vomited, and the pain and sickness continued till the evening, when he became comatose, and died at ten p.m., having shown no signs of paralysis till just before death.

*Post-mortem examination sixty-four hours after death.*—Almost the whole of the left corpus callosum was occupied by an immense extravasation of blood, surrounded by softened brain more or less infiltrated with blood. In the centre was a portion quite loose of more solid consistence, which, when removed, and cut through, exhibited a central vessel, of the diameter of a probe, surrounded by fibrin a line in thickness. Upon maceration, the mass was found to consist apparently of a portion of brain infiltrated with blood, and not of a coagulum, for numerous vessels could be seen with open orifices on the divided surface, and a microscopic examination also exhibited the minutest capillaries in an unaltered state. Though the extravasation was so extensive, it had not penetrated the ventricle, and the rest of the brain and its vessels were quite healthy. Dr. Ogier Ward attributed the origin of the sudden purpura to the fright on the 14th, as he had known a similar effect produced in a child in the course of a few hours, from a similar cause. He considered the ineffectual straining at stool to have been the efficient cause of the extravasation, which, by its gradual advance, prevented any rupture of the substances of the brain.—*Lancet*.

#### ORIGINAL COMMUNICATIONS.

#### TWO CASES OF SUPPOSED POISONING BY CORROSIVE SUBLIMATE.

By J. ROBINSON, L.R.C.S.I. and K.Q.C.P., of Ballibay.

On the 23rd of September last, I was called on to visit Margaret Plunkett, aged 50, whom I found affected in the following manner—viz., profuse salivation, teeth and gums black, mouth much ulcerated, and in some places sloughing, great difficulty in swallowing, burning heat and pains in œsophagus and stomach, and high mercurial fever. On inquiry, I found that she and another woman named Mary Smyth, having complained of dyspeptic symptoms to a man named Donnard, a pig-doctor in the neighbourhood, he volunteered to give them something useful, or as he expressed himself, "*a few grains which would effectually clean out their stomachs.*"

This substance, which was sworn by Plunkett to consist of hard, whitish solid grains, amounting altogether to about the size of a pea, was mixed in a glass and a half of spirits: half of this was taken by Smyth ten days previous to my visit, and the remainder, containing some undissolved particles, was administered to Plunkett. The latter stated that in the act of swallowing it she felt great heat in her mouth, throat, and stomach, and that vomiting came on immediately, followed by purging, both of which contained blood. Salivation set in a few hours. The vomiting and purging continued almost constant till her death, the stomach scarcely retaining anything. The alvine evacuations were mixed with blood only at intervals. She suffered much from violent pain in her stomach and bowels, also from pains in her joints. She gradually sank from fever, irritation, and exhaustion on the twenty-second day from the receipt of the poison. The fever, towards the close, assumed a typhoid character. Deceased was naturally of delicate constitution, and for some time had been affected with ordinary dyspepsia, but able to follow her usual occupation.

*Post-mortem appearances thirty-six hours after death.*—The body was found small and emaciated; mouth livid; ulcers healed, their site presenting a silvery gray appear-

ance; tongue covered with a thick, rough brownish coat like leather; the pharynx and upper part of the œsophagus was lined with a coating of lymph, which was easily detached in the form of a tube two or three inches long; no abnormal appearance in stomach; duodenum, cæcum, and rectum congested; gall-bladder contained five or six ounces; urinary bladder quite contracted.

*Case 2.*—Smyth was affected by the poison in the same manner as Plunkett, but not to the same extent. The first effects of the poison were similar and immediate, but the vomiting and the purging were not so great. On my first visit I also found her profusely salivated, and her mouth ulcerated. Being a strong healthy woman, she recovered in about three weeks.

As Plunkett made a dying declaration to the effect, that she saw Donnard mix some ingredient in whiskey that Smyth afterwards administered to her, and which was the cause of her illness, both these persons were indicted for manslaughter at a late assizes.

At the trial, Eliza Duffy, with whom Plunkett lived, proved that Donnard came into her house on the evening preceding that on which the poison was taken; that they were all drinking together; that she heard Smyth say to Donnard to keep as much whiskey as would do to mix the medicine; that on the following morning she overheard Smyth and deceased talking while taking it (which the latter was at first unwilling to do); that Donnard called a few days afterwards with a wash for Plunkett's mouth, stating at the same time that she (Plunkett) had made too free with the medicine he had given; that from the time it was taken, deceased got gradually worse, and died from its injurious effects after three weeks illness, although she had previously been in ordinary health.

The crown tendered as evidence a dying declaration made by deceased, strongly implicating the prisoner Donnard, which, however, was ruled by the judge as inadmissible, on account of her informations having been made out the day previous, and only a copy of the original sworn to before a magistrate.

When the medical evidence was called on, I was asked if, from the symptoms and post-mortem appearances, I could say what was the cause of death, I stated that in my opinion death was caused by a mercurial irritant. I was then asked could I say what substance that was? I said not without taking into consideration the description given of the poison by deceased in her dying declaration, and its effects previous to my visiting her. The judge said that an opinion founded on what would not be admitted as evidence could not be received. The prisoners were ultimately acquitted.

The foregoing is interesting in two points of view—1st, an acquittal, notwithstanding the clearness of the case; and 2nd, the substance administered, and the quantity which proved fatal. With respect to the former, the deceased distinctly swore, in presence of a magistrate and police officer, that she expected what was prepared by one prisoner, and administered to her by the other, would prove fatal. In this and in the effects produced by the drug, she was corroborated by the witness Duffy: to the latter the male prisoner even admitted indirectly that it was he who gave the poison. These, together with the fact that both persons who partook of it, were severely and similarly affected, should, I think, have made the case a very clear one indeed. In summing up the evidence, the judge stated to the jury, that Donnard's remark, with respect to the deceased having taken too much of what he gave, tended in his favour, as it was clear that she had not followed his instructions as to taking it. From this we may infer that ignorant and unprincipled persons are at liberty to prescribe dangerous medicines with impunity.

Now with respect to what the poison was, I have no hesitation in stating that I consider it to have been corrosive sublimate. I think the description given of it, its immediate effects, and the symptoms I saw produced, leave no doubt on that subject; besides, it is commonly used in the country by persons practising on the brute creation. As

to the quantity, the size of a pea would vary from fifteen to twenty grains; suppose, therefore, the deceased took rather more than one half of this, her share would probably amount to from eight to twelve, which would be a comparatively small dose to prove fatal to an adult, considering that it was only partially dissolved and that immediate vomiting came on: however, as it was taken early in the morning, I presume it was on an empty stomach.

### WHAT IS THE ACTION OF EMETICS ON THE HORSE?

By JOSEPH SAMPSON GAMGEE, Esq.,  
Student in Medicine in University College, London.

It is so well-known among veterinary pathologists, that the horse is not acted on by emetics as is the dog, that, while they frequently prescribe them in the diseases of the latter, they never do so in those of the former. The most celebrated writers on veterinary therapeutics, generally exclude emetics from the list of medicines available for the relief of the diseases of the horse, and refuse to the emetic, *par excellence*,—the potassio-tartrate of antimony,—any emetic virtue in the equine species, when administered internally. Were this the sum total of our information on the point at issue, our inquiry would be at an end; but since it has been alleged by several French experimentalists, that the horse makes efforts to vomit when potassio-tartrate of antimony is injected into its veins, it is imperative that we should test the empirical grounds of such allegation.

We find it stated by M. Dupuy that he has succeeded in producing attempts to vomit in the horse, by injecting tartar emetic into the crural or jugular veins, in doses varying from six grains to two drachms. The director and professor of the Veterinary School at Lyons, in their account of the action of tartarized antimony, thus express themselves:—"Injected into the veins of the large herbivora, in doses of from nine to eighteen grains, tartar emetic occasions vomiting, or the phenomena which accompany that act of evacuation." They give no evidence to prove this statement.

Finally, we have to quote an experiment which was performed by MM. Leblanc and Mignon:—"Thirty-six grains of tartar emetic injected into one of the jugular veins of a horse,—a longitudinal opening about seven inches long, made on the side of the linea alba,—exploration of the stomach with the finger,—contractions of the viscus insensible,—contraction of the abdominal muscles alternating with that of the diaphragm, the latter taking place during inspiration; at this moment the right crus of the diaphragm is forcibly extended, but the œsophagus is only moderately compressed between its fleshy lips,—the intestines forcibly escape through the wound in the abdomen,—eight minutes after this injection of tartar emetic, appearance of some nausea, or violent and simultaneous contraction of lower abdominal muscles and diaphragm. The whole intestine is removed in order to see the stomach well; the viscus follows, like a pendulum, the alternate movements of contraction and relaxation of the diaphragm; the stomach, which is tolerably distended, is the seat of slow, continuous contractions, which always commence at the same point, the pylorus. The contraction and relaxation of the lower abdominal muscles and diaphragm take place gradually and slowly. This partition yields little by little, but uninterruptedly, to the abdominal muscles; these act similarly with regard to the diaphragm, so that if we form a material idea of these respiratory powers, we can compare them to two machines always equidistant, and directed in the same course, each describing the half of a double cone, whose limited base of reciprocal excursion would be in the middle. When one of them is at the summit, the other is at the base, and *vice versa*; consequently, the action of the diaphragm increases in proportion as that of the abdominal muscles diminishes. These forces are therefore essentially respiratory. The one—the diaphragm—is active during inspiration; the other—the force generated by the abdominal muscles—is

expiratory. Renewed, sudden, violent, and simultaneous contractions of the diaphragm and abdominal muscles occur; the latter even appear to augment their action in proportion as the diaphragm relaxes; it is the nausea, or the manifestation of the effort. No vomiting has occurred; finally, the animal expires."

From this account it appears that, on seeing violent efforts of the abdominal muscles and diaphragm of a horse, into whose veins tartar emetic had been injected, and from whose abdomen all the intestines had been removed through a large opening, MM. Leblanc and Mignon inferred that the emetic was producing its specific action by exciting efforts to evacuate the stomach through the œsophagus. No vomiting occurred, and therefore the experiment, *primâ facie*, establishes,—firstly, that the horse makes efforts to vomit when potassio-tartrate of antimony is injected into the veins; secondly, that as those efforts are not followed by vomiting, there must be some mechanical impediment to the escape of matters through the cardia. Both these conclusions are erroneous; and they are so for the following reasons. The description given of the movements of the abdominal muscles and diaphragm, is not such as to prove beyond doubt that they were efforts to vomit. Confessing adhesion to the doctrine that the diaphragm takes an active part in vomiting, we deny that it does so by virtue of an *inspiratory movement*, and that, as it *relaxes*, the abdominal muscles make a sudden effort, as in forcible expiration. The act of vomiting is one *sui generis*, and not a respiratory act.\* Let any one try to simulate the effort to vomit, or study the real effort in his own person, and he will feel that the glottis having been closed after a deep inspiration, the diaphragm and abdominal muscles act simultaneously, so as to press the stomach between them. To this it may be objected that, for the diaphragm to descend while the glottis is closed, the air in the chest should be rarefied, which is an unlikely occurrence. The fallacy of this objection is demonstrable by experiment, as Dr. Sharpey has long since shown in his lectures on anatomy and physiology in University College. A bandage being closely passed round the lower part of the chest, it is easy to press down the diaphragm at will; on doing so, the bandage becomes loose, evidently owing to drawing in of the cartilages of the lower ribs by the descending diaphragm. Thus the augmentation of the thoracic cavity in its long axis, is compensated by its decrease in the transverse; and it becomes obvious that the diaphragm may descend when the glottis is closed, without enlarging the chest, and therefore without rarefying the contained air. That, however, the witnessed efforts were in reality the pangs of death, is rendered more than probable by the terms in which the narrative of the experiment ends,—"*enfin, l'animal expire.*"†

But conceding, for the sake of argument, that the movements observed were efforts to vomit, we maintain that it is not just to conclude that, because they were not followed by vomiting, there must have been some mechanical obstacle to the escape of matters through the cardia. As the experiment was performed, it was impossible for the stomach to be pressed upon by either the abdominal mus-

\* Since the terms in which M. Mignon has related his experiment may leave some doubt as to his idea of the nature of the movements in vomiting, it may be cleared up by his ulterior exposition of that idea. "*Ce phénomène (le vomissement) commence aux derniers termes de l'inspiration pour finir dans l'expiration. C'est dans ce dernier temps ou pendant le relâchement du diaphragme qu'a lieu le rejet des matières sans aucun doute; mais c'est dans l'inspiration, ou par le fait d'une violente et brusque contraction du diaphragme, aidé de l'action des muscles abdominaux, que l'estomac verse son trop-plein dans l'œsophage.*"—*Op. cit.*, p. 244.

† As the performance of such experiments in horses renders it indispensable that they should be thrown on the ground and secured, great caution should be observed in interpreting the muscular efforts; for when a horse is cast he struggles violently for liberty, even before a bold stroke of the knife has made a gash seven inches long into its belly, and all the bowels have been removed.

cles or diaphragm, and therefore there was no chance of its contents being evacuated through the œsophagus. Protected, as the horse's stomach is, by the far-back projecting ribs, it can only receive pressure from the abdominal muscles, indirectly, through the intestines. When these are removed, the viscus cannot be pressed upon by those muscles, and the pressure of the diaphragm on it is very slight because the stomach undulates like a pendulum, backwards and forwards, in the empty cavity, without meeting with the least resistance.

The evidence which we have adduced, and which is all that we have been able to collect, in favour of the doctrine that efforts to vomit can be excited in the horse by injecting tartar emetic into its veins, may be thus briefly summed up:—1. M. Lecoq and his colleagues (the veterinary professors of Lyons) have expressed an opinion in the affirmative, without publishing the grounds of their belief. 2. The experiment of MM. Leblanc and Mignon, which professes to prove the doctrine, appears to have been conducted with so little regard to the exclusion of sources of error, that it would be unwarrantable to draw any positive inferences from it. 3. As we are not acquainted with the details of the experiments which formed the basis of M. Dupuy's statement in support of the above doctrine, they need confirmation; a need which becomes imperative, on reflection that the horse is not susceptible of emesis by the introduction of any medicinal substance into the stomach, and that as our knowledge of the action of emetics in the dog proves, that when introduced into the veins or into the stomach their effects differ in degree and not in kind, there is strong ground for the belief that the horse is unsusceptible of the specific action of emetics, even when directly injected into its circulating system.

In order to settle the question, I determined to appeal to experiment, and procured for the purpose a horse and a mule, both of sound constitution. I have injected into their jugular veins solutions of tartar emetic, in 5, 30, and 50 grain doses, but have never seen efforts to vomit; to avoid misunderstanding I may say, that I have never seen any such thing as the animals thus experimented on take a deep inspiration, fix the chest, and make sudden and forcible exertion with the abdominal muscles. Inasmuch, however, as I noticed some preternatural phenomena of muscular action in two of the experiments, a detailed account of them is rendered necessary. Twenty minutes after injecting into the left jugular vein of a horse thirty grains of tartar emetic, dissolved in three ounces of water, the muscles generally became rigid; but there was no movement caused by any of them. It was static, not dynamic contraction. After this, I noticed a good deal of twitching of the muscles of the fore and hind limbs, and of those of the lower part of the neck; but the abdominal muscles acted evenly, though with more frequency than usual, as the respiration became a good deal accelerated. At the end of three hours the twitching had almost ceased, and had done so completely; and the animal had resumed eating in a little less than four hours.\* Lest it should be feared that I misconstrued the phenomena of muscular contraction, I may say that almost every five minutes, and sometimes oftener, I took notes of the state of the animal; and did not note such words as *spasm* or *effort*, but avoided the danger of erring in judgment by describing in phrases all I saw. It is important to notice that in the same animal, on a subsequent day, I injected 30 grains of tartar emetic in 1½ oz. of water, without producing any sensible effect whatever. I injected 50 grains of tartar emetic, dissolved in 1½ oz. of tepid water, into the jugular

\* A few minutes after I had injected the tartar emetic, the animal commenced purging, and continued doing so for an hour and a half. To determine whether this phenomenon was due to the tartar emetic or to the water, I injected three ounces of tepid water into the jugular vein of a mule—it had no effect: but purging was occasioned in fourteen minutes by injecting into the same vein, after the lapse of an hour, six ounces of tepid water. In none of my subsequent experiments was this purging produced,—a fact which needs further experience for its explanation.

of a mule, with the following result. Fourteen minutes after the injection, the animal did not present any change; but, in a few minutes more, left off eating and stood still. In the ensuing thirty-seven minutes, the muscular system was several times subject to momentary rigidity, which, with the exception of slight elevation and extension of the head, was unaccompanied by any movement. This muscular rigidity simulated the tetanic state, and contrasted strongly with the state of the muscles of the same animal while voiding fæces and urine; in an hour and fourteen minutes the mule resumed eating, and presented no other symptoms. If I had been a little less cautious in the avoidance of fallacy, it is very likely I should, in observing these muscular phenomena in two of the experiments, have succeeded in seeing attempts to vomit; but they assuredly were not such, for they did not in any degree resemble the efforts made by the same animals to evacuate the bladder and rectum, or the efforts made by the dog and man to empty the stomach through the œsophagus.

Considering the vague manner in which M. Dupuy alludes to his experiments, and, on the other hand, confident of the fairness with which my own have been conducted and recounted, I feel myself justified in opposing my conclusions to his, and in stating that all the attempts hitherto made to excite efforts to vomit in the horse by emetics have failed. This unsusceptibility to emetic action, and the very rare manifestation of the phenomena of vomiting by the horse, must obviously be regarded as cause and effect, and consequently, as the answer to the question, Why does the horse rarely vomit?—*London Jour. of Med.*

#### REMARKS ON THE TREATMENT OF BURNS AND SCALDS.

By W. J. MOORE, Esq.,

Resident Surgeon to the Queen's Hospital, Birmingham.

THE satisfactory termination of a burn or scald will often depend on the mode of treatment adopted when the patient is first brought under the care of the surgeon, not only as regards the constitutional measures taken, but also the external applications then had recourse to. The numerous dressings which, from time to time, have had their advocates, undoubtedly act much in the same manner, preventing exposure to the atmosphere; but from their plurality it becomes somewhat difficult to make a selection of that most appropriate, especially as many are recommended, backed by an equality of testimony and evidence. In making such selection, guidance should be taken, not from the reputation which such and such an application may happen to possess, but rather from the characters of the burn itself; injuries of a moderate nature requiring different, and perhaps more careful, treatment in the first instance, than those of a more severe description.

Probably few things are more distressing, both to the witnesses and the sufferers, than cases of bad burns; and this remark is not only applicable to the time when the burnt part is undergoing cicatrization, but tells with double force when, from contractions and loss of integument, an eye is rendered almost useless, a limb becomes an absolute incumbrance, or the chest and chin unite. Happily such cases are now rare; but frequently and notwithstanding the greatest care, some approach to such a state is inevitable. It is, therefore, of consequence that any treatment tending to obviate these unpleasant results should be propagated and made known as universally as possible.

Nearly three years back, Dr. Steward, who was then my colleague in this institution, first recommended and brought into practice creosote oil as an application to burns and scalds. I at that time bore testimony to Dr. Steward's estimate of its worth, and gave in one of the periodicals my opinion of its mode of operation when employed in such cases. Subsequent experience, without diminishing my faith in its efficacy as an application, has, however, led me to use it only in a certain class of cases; and the same experience has also led me to make use of other applications, which perhaps I may feel justified in recommending to notice.

Of course a burn or scald denotes inflammation, which inflammation is followed by its necessary consequences, precisely ■ though set up by a totally different cause; the first indication, therefore, is to keep down such action, and limit the mischief which may probably arise. And for a very slight burn or scald this object cannot be better fulfilled than by the constant employment of cold; and as an application in such a state nothing can be better than water, to which a small quantity of ether or spirit has been added; or, otherwise, ■ piece of metal—brass or lead—will be found ■ very convenient substitute. This plan of treatment, however, will not do if much of the surface be injured, and it then becomes necessary to use an application which will both afford some degree of stimulus to the part and aid in relieving congestion of internal organs. Such an application presents itself in creosote oil, and it is in burns of this description where its use is most successful.

Supposing a person to have the misfortune to burn some part, say, for instance the forearm and hands; supposing the burn to be of that character which may be said to partake of the first and second degree of intensity, having several blisters already formed, I should recommend, and have practised with great success, the following treatment. Any vesicles present are to be first punctured, and the parts then dressed over with creosote oil by means of a feather or brush, and allowed to remain exposed a short time. This generally has the effect of immediately relieving the pain, which perhaps may be due to the coagulation of the albumen contained in the serum thrown out by the creosote; which fact is rendered apparent by the formation of a white film wherever the oil touches the abraded surface. It thus prevents the contact of the air. A minute or two having elapsed, the dressings should be repeated, and the whole parts (if the hands) enveloped in strips of linen, slightly oiled, with a bandage over all, for better security of the dressings. In such a case as the one supposed, the cure will be complete in two or three dressings; and it is well worthy of notice, that if the creosote oil is applied soon after the receipt of the burn, it will effectually prevent any large amount of vesication.

I have recommended envelopment in oiled linen after the application of the creosote, on account of the situation of the parts supposed to be injured, but the effect is equal, and in some cases more marked, when no other application whatever, excepting the creosote oil, is used. Should the leg be the part burned, and the patient be able to lie by for some time, I should not use anything except the creosote; either preventing contact of the clothes by means of a cradle (if the patient, as is the case in an hospital, can be made to lie in bed), or otherwise by means of a sort of funnel, composed of cane hoops and linen, easily adapted round the limb. The application of the creosote should then be performed twice a day. The parts where there are no vesications are well at the second dressing, and the vesicated parts become covered with coagulated serum, which forms a scab, and makes the best protection which can by any possibility be devised. The cure is thereby rendered easy, painless, certain, and without smell, and the scab in ■ short time becomes detached from the newly healed surface. I have treated large portions of the leg, thigh, and body in this way; the scabs formed gradually, shelling off from the circumference inwards, but of course it is always proper to prevent, if possible, the loss of the cuticle, which is very liable to be rubbed off during conveyance to an hospital, removal of clothes, &c. This treatment is peculiarly applicable to burns of the face where there is difficulty in retaining any dressing. The oil, however, may be easily applied, the only care requisite being that it does not enter the eyes, as from its stimulating properties it would cause great pain, and perhaps some degree of inflammation; should this accident happen, it is best to bathe the eye immediately with a little water. Many persons have expressed to me their fears for the consequences of not covering the parts, otherwise than by the creosote, particularly when, as sometimes happens, the patient is obliged to go out into the open air immediately afterwards; more covering, however, is not at all neces-

sary. Burnt faces frequently are dressed and sent away exposed, and without any bad results. One case particularly intrudes itself into my recollection, which strongly illustrates this fact:—A man applied during the winter of 1849, having his face burnt by an explosion of gunpowder. He was dressed with creosote, and taken into the ward; he, however, would not stop, and starting off home walked a distance of upwards of four miles, there being at the time a high and bitterly cold wind. When he presented himself next morning he stated he had felt no pain from the exposure, the film of coagulation having effectually acted as a preservative against the piercing blasts. He continued his visits to the hospital until cured, and was exposed in like manner every day.

I trust enough has been said to prove there is some efficacy in this mode of treatment; and should any feel disposed to give it ■ trial, I fancy they will not be disappointed regarding the results.

I occasionally, however, treat burns in ■ different manner; but, as I said before, am regulated in my application by the character of the injury. A very good plan is to apply a thick solution of gum, allowing it to dry on the parts, which it speedily does, forming a kind of mail coat, which also acts effectually as a preservative from the atmosphere. This, when dry, cracks, and in a few days peels off, leaving the parts more or less healed. This is a very good mode of treatment when the smell of creosote is strongly objected to, which idiosyncrasy is sometimes met with. Another very good application, and one which I can recommend, is an ointment containing a proportion of hydrocyanic acid, or rather, more properly speaking, a liniment; my application being composed of olive oil, hydrocyanic acid, and fresh lard. The value of the application evidently consists in the hydrocyanic acid allaying the pain, which it does to ■ great degree. Probably the virtue of the famous quack remedy, the laurel ointment, depends on the same cause.

When called upon to treat burns of the third degree, where sloughing and loss of substance is inevitable, as it matters but little what application is made use of in the first instance, I generally smear the parts with some oily material, or carron oil, if procurable, and then envelope them in a flannel roller. This is allowed to remain for some days, until suppuration has commenced, when it is removed, and either ■ poultice or lint, soaked in lukewarm water, used in its stead. The ulcers which result of course must be dealt with according to approved surgical principles; but they will be, under any treatment, sufficiently troublesome. The chief point is to repress the exuberance of the granulations, which tend to render the cicatrix unsightly, and also retard that desirable process; while padding and splintering must also be kept in view, to prevent the lamentable contractions so disposed to take place. I may here also observe, that, consistent with cleanliness, the less frequently ■ burn is dressed the more likely will the patient be to progress favourably, as frequent exposures are thereby avoided. And I am also persuaded, that when ■ large surface has suffered, only a part of that surface should be exposed at one time; *nimia diligentia* in the treatment of burns is thoroughly deprecated.

Not the least difficult part in the management of a case is the internal treatment, when a burn or scald is of a severe description. The shock to the system is exhibited by the shivering, paleness, weak pulse, or perhaps stupor, present, and imperatively calls for brandy, wine, or other stimulants. In slighter cases, however, warmth to the feet and a little warm tea only are requisite. Perhaps the most danger, particularly in children, occurs about the fourth day, when the lungs frequently become congested, and difficulty of breathing results. Antiphlogistic treatment must then be adopted, and leeches applied to the spine, with antimony internally, perhaps combined with compound tincture of cardamoms or sulphuric ether. It is believed several lives have been saved by this treatment, which would have been sacrificed had stimulants been altogether persevered with as frequently advised.

There is one drug which is frequently recommended in

burns—viz., opium; but it is for the most part unadvisable, adding as it does to the congestion and stupor already present. The only time when it appears to be proper, is when diarrhoea has supervened; when it frequently produces great comfort, and is evidently productive of good. Hyoscyamus is the preferable drug should a sedative be wished for in these cases.—*Prov. Jour.*

#### A CASE OF CYSTITIS, ACCOMPANIED BY GANGRENE OF THE LOWER EXTREMITIES.

By HENRY MELVILLE, M.D., Toronto.

THE following report of a remarkable, and, I believe, unique case, is defective in many particulars, arising from the impossibility of obtaining an accurate medical history of its commencement and progress up to the period at which I first saw the patient; but such as it is, I offer it to the profession as a contribution to pathological science, not altogether devoid of interest and importance:—

J. G.—, aged 38, a native of Yorkshire, England; he emigrated to Canada when he was eight years of age, and had resided there since; had been married seven years, and had two children, one of whom survives—a boy, exhibiting the scrofulous diathesis strongly marked, which he does not apparently derive from his mother, who seems to be a healthy person. He is represented to have been a stout, plethoric, and active man, of a sanguine temperament and lively disposition, enjoying uniformly good health, until within the last three years; of good habits, living generously, and rarely exceeding either in food or drink. His occupations have been various; for some time past he was employed as salesman and general porter in an extensive dry goods store in this city.

About three years ago he was engaged one day lifting a stove, in company with another man; while in the act of taking it down a flight of steps, his companion, who was below the stove, from some cause relaxed his hold, and the whole weight was thus thrown upon him to sustain. In the exertion required to effect this, he felt something snap in the left groin, and subsequently observed a swelling, which occasioned him much pain and discomfort at the time; the inconvenience attending its presence wore off after some months, although the swelling never entirely disappeared. During this period he had frequently suffered from occasional discharges of purulent matter from the urethra, which were generally preceded by an enlargement and followed by a subsidence of the swelling, with a sense of relief of distress. He also experienced occasionally a sense of irritation about the neck of the bladder, with difficulty of micturition, but not to such an extent as to occasion any suspicion of stricture of the urethra. During the early part of the past winter, he complained frequently of cramps in the lower extremities, affecting principally the muscles of the left leg, and felt frequently very chilly, with alternate “flashes of heat.” He was also observed to become more irritable in his temper, and was the subject of occasional fits of waywardness and despondency, expressing himself as feeling wearied, and less able to endure fatigue or exertion. His bowels were usually constipated, and the small size of the faeces were the subject of remark to himself and wife. His appetite was capricious, and he became rather more unsteady in his habits, drinking gin, with the assertion that it relieved much of his uneasiness. In the early part of March last, his occupation required him to be much on his feet, standing frequently the whole day long. On the evening of the 12th he had indulged somewhat freely in company with some friends, but retired to rest at his usual hour, without any additional complaint or suffering. On the morning of the 13th he rose at his usual time and dressed himself, but in stooping to pull on his boot, he was seized with violent pain in the left foot; it was so intense as to render him quite faint, he staggered to a seat, and after a time was restored to consciousness by the use of stimulants. On attempting to walk, however, supported by attendants, it was discovered that he had lost the use of his left leg; it was also observed that the toes and foot

had become colourless, and that the extensor tendons were very rigid. Under the impression that he was suffering from an attack of rheumatism, warm and stimulant applications were applied, with some degree of relief of the pain and restoration of heat of the part. On the 14th, a red spot was observed on the dorsum of the foot, the toes withered away, and the foot and leg became gangrenous. After a few days, the right foot also put on a gangrenous appearance; he suffered from occasional paroxysms of pain in both extremities; there was partial retention of urine, but he would occasionally void it in considerable quantities.

Such is the history of the case that I have been able to trace from the account given by his wife and other attendants; many of the particulars, however, were not revealed till after his death.

On Sunday, the 4th of April, I saw him for the first time. He was in the semi-erect posture in bed, supported by pillows, with the body inclined to the left side, resting principally upon the left hip; his countenance extremely pale, and expressive of great anxiety and distress, the latter being further evinced by groaning and sighing. His face and hands were bathed in a profuse perspiration; he suffered from great restlessness and want of sleep, with much pain in the left thigh and right foot; his pulse was quick, small, and thready; his tongue dry and brown, and his general sufferings were aggravated by excessive thirst. The left leg was lying on the outer side, bent at the knee, the thigh being also flexed, on the body. The toes and foot presented all the characters of dry gangrene, and the gangrenous inflammation extended to the upper third of the leg posteriorly, and nearly as high as the head of the tibia anteriorly; there was a faint attempt at the formation of an irregular line of separation; below this line the limb was cold and spongy, the foot and toes being hard and dry. The thigh was very oedematous, and there was an inflammatory blush extending above the popliteal space to the lower third of the thigh posteriorly. I thought I could detect a faint pulsation in the upper part of the femoral artery, but from the great oedema this was difficult to ascertain. The right leg was placed on the inner side, was also oedematous, and was in a flexed position. The gangrene of the right foot was confined principally to the under part of the toes, the sole of the foot, internal malleolus, and heel, the inflammation extending as high as the middle of the leg. I ordered warm spirit lotion to this foot, and a yeast poultice to the left leg; I also advised the free use of wine or porter, and nourishing broths. I prescribed a mixture containing the liquor ammon. acetatis, carbonate of ammonia, and camphor mixture; with five-grain doses of quinine. The prognosis, given to the family at his request, was of course of the most unfavourable character. I confess that I was entirely at a loss to account for this extensive destruction of vitality, as on investigation I could discover no adequate exciting cause. Attributing it in the first instance to the effect of cold and exposure, I was assured that he had not been in any way subjected to their influence, as he always wore ample and warm covering to his feet and limbs. I was told that he had not been indulging to any great extent, except on the evening preceding his attack, and that then he had only taken more freely of his customary drink, but not to such an extent as to render him intoxicated; that his food had been of the best description, and indeed somewhat choice for a person in his circumstances.

On the following day, I expressed a desire to have a second opinion on the case, and with the sanction of the family I requested my friend Dr. Hodder to visit the patient with me. On a careful examination at this consultation, we ascertained that there was really no pulsation in either femoral artery, and detected the existence of a tumour in the left iliac region, filling completely the left pelvic fossa, and extending as far as the median line, and nearly as high as the umbilicus. We could trace its outline distinctly; it conveyed an indistinct sensation of fluctuation; was apparently moveable; was resilient; dull on percussion, and did not exhibit any indications of pulsation; the surface was uniform, and there was no tender-

ness on compression. Subsequent inquiry elicited the fact that on the morning of his attack he was conscious of "something having given way," and that then he had first discovered the increased size of the swelling in the groin.

The diagnosis was most obscure. Several of my professional friends visited the case, and various opinions were formed as to the nature of this tumour. Its existence at once solved the mystery of the gangrene, and confirmed the prognosis. My own impression was that an aneurism had originally existed, the coats of which had given way, and the contents become diffused and coagulated. Another thought it was a sarcomatous growth, the opinion as to its malignant nature being certainly countenanced by the general appearance and complexion of the patient, which would have indicated the cancerous diathesis under other circumstances. A third regarded it as an encysted tumour, and a fourth suggested the idea of abscess. Influenced by these varied views of the case, and desirous of establishing the diagnosis in order that, if practicable, an attempt should be made to restore the circulation by preventing the pressure occasioned by this tumour, either by its removal or the evacuation of its contents, it was contemplated to puncture with an exploring needle, even at the hazard, had it proved to be an aneurism, of the necessity of ligation of the common iliac, or even the aorta—an extreme measure which the desperate condition of the patient might have justified. The rapid sinking of the patient, however, on the day when it was resolved to make the experiment, prevented the proceeding: a circumstance which subsequent revelation proved to have been very fortunate as regards what might probably have been the issue of it. One circumstance is worthy of remark, that during the period I attended him there was no clue given to lead to a suspicion of the bladder being implicated; for although he complained occasionally of retention of urine, this was by no means urgent, and he was as frequently relieved by warm diluents, voiding considerable quantities of urine several times; and it was attributed to the constitutional irritation produced by the prominent disease. It is unnecessary to trace the progress of the case to its fatal termination, the symptoms being such as usually attend extensive destruction of the tissues. He died on the 18th of April, fourteen days after I had first seen him, and fifty days from the commencement of the attack. The tumour had increased in size, extending over to the right side, and filling the cavity of the pelvis completely, rising at the same time as high as the umbilicus. I could not obtain permission to examine the body while in the house, but the opportunity was afforded of doing so in the vault of the cemetery. The inconvenience of conducting the post-mortem under these circumstances, prevented as full an examination as could be desired, and we were not permitted to open the head. On making the usual incisions for exposing the contents of the abdomen, the intestines presented a healthy appearance, but were pushed upwards by a tumour filling the entire pelvis and lower part of the abdominal cavity. Its contents were now readily perceived to be fluid, and it was discovered to be an enormously enlarged bladder distended with urine. It was firmly attached to the brim of the pelvis by strong adhesions of cellular tissue, binding down the aorta at its bifurcation and the upper portion of the rectum against the projecting lumbar vertebra; both iliacs and the middle sacral arteries were filled with a firm coagulum; in the left, which was traced, this coagulum extended through its divisions and along the femoral; the ureters were much enlarged, being nearly the size of a finger; the bladder was found to contain fully four pints of urine, and was not as fully distended as its capacity would admit of; a circumstance accounted for by the frequent involuntary evacuations which preceded immediate dissolution. The rectum was much diminished in size; the neck of the bladder was buried in a mass of condensed cellular tissue, completely infiltrated with lymph, resembling a solid mass of diseased structure. The coats of the bladder were much thickened and soft, the mucous coat being thickened and plicated; the fundus and anterior portion of the body were free and capable of

extension. These appearances would seem to justify the opinion that the case had been one of chronic cystitis of long standing, commencing probably at the period of the first injury received, three years before, and is an evidence of the fact that inflammation of this viscus may exist in a chronic state, and be purely local in its character for a considerable time, slowly producing great changes in its tissues, unrevealed by any very prominent indications of disease.

The length to which I have already extended this article, precludes me from adding more than that I have not yet found in the books which I have been able to consult the record of a similar case presenting the pathological conditions here detailed. There are many points of practical importance involved in its history, but these I must reserve as the subjects of reflection and future comment.—*Upper Canada Journal.*

#### REVIEWS AND NOTICES OF BOOKS.

**INSANITY: ITS CAUSES, PREVENTION, AND CURE**, including Apoplexy, Epilepsy, and Congestion of the Brain. By JOSEPH WILLIAMS, M.D. 2nd Edition. London. 1852. Small 8vo. pp. 317.

THIS is the second edition of an essay to which the Lord Chancellor's prize was awarded some years since by the President and Fellows of the King and Queen's College of Physicians; the subject offered for competition having been—"The use of narcotics, and other remedial agents, calculated to produce sleep in the treatment of insanity." The present volume may, however, be regarded as altogether a new work, having been almost entirely rewritten, and enlarged to more than double its former size; and while the former edition was necessarily limited to the subject-matter offered for competition, this constitutes a complete treatise on insanity and its treatment.

The volume commences with some general observations upon insanity, followed by a pretty full account of its causes. The classification followed by the author is similar to that adopted by the Commissioners—viz.,

##### "1. Mania:—

1. Acute mania, or raving madness;
2. Ordinary mania or chronic madness being less acute.
3. Periodical mania, or remittent mania, with comparatively lucid intervals.

##### 2. Dementia, or decay and obliteration of the intellectual faculties.

3. Melancholia,
4. Monomania,
5. Moral insanity,
6. Congenital idiocy.
7. Congenital imbecility.

} Partial insanity.

##### 8. General paralysis of the insane; epilepsy; delirium tremens."

"In addition to these, it is our duty (the author observes) to add puerperal mania, which has been excluded from the above classification, as such cases are very properly not considered suitable to be sent or to be admitted into an asylum."

The treatment of insanity occupies by far the larger portion of the volume. This part commences with some remarks respecting the signing of certificates; and in it we find some useful hints as to the mode of questioning patients supposed to be insane. "The generality of medical men (Dr. Williams observes) when asked to see a case, go with the full intention of establishing insanity, not to disprove it. The object should not be to look for the evidence of insanity, or for that evidence which may furnish mere *suspicion*; but the great point is to ascertain whether the individual is dangerous to himself or others; and in some instances, whether partial surveillance is necessary to prevent a waste of fortune or of effects."

"If, on visiting a person, he is at once found to be evidently of unsound mind, the question to be decided is, what degree of restraint may be necessary; and this must depend upon a variety of circumstances, all of which should be ascertained, particularly respecting his hallucinations, or instinctive wish, his habits, actions, and inclinations.

When a patient, in a calm and placid manner, complains of

unjust detention, or charges his friends with dishonest intentions, this, although so common among lunatics, should not be disregarded, but a thorough investigation should be instituted; and it is more proper to judge by the facts and appearances themselves, rather than from any opinions voluntarily tendered by others. It may happen that the unsound state of mind at once betrays itself, but still it is a duty to examine individual cases, because, as numbers have already been proved to have been placed under confinement from interested motives, the same delinquencies may again occur."

"There can be no doubt (Dr. Williams observes) as to the necessity of placing under control a furious maniac, who would be likely to injure himself or others;" but "there cannot be a doubt (he adds) that numbers, now the occupants of lunatic asylums, ought never to have been subjected to such imprisonment."

"How often is a man sent to an asylum by his friends because he is eccentric or irritable; whereas by removing him from home to some suitable and cheerful residence, and by having an experienced servant to wait upon him, he might, by temporary change and care, again in happiness return home to resume his usual duties; but he is sent to an asylum, which Dr. Conolly says 'is the worst place for an eccentric or irritable man, as here this eccentricity, this irritability increases; whereas in general society these failings should be checked. Confinement renders it permanent, and ripens eccentricity or temporary excitement or depression into actual insanity; and this is not the worst part of the evil, for even when a patient has suffered no aggravation of his disorder during its greatest severity, the danger is not passed; nay, it is increased as his convalescence advances; for where that otherwise happy change commences, the sights and sounds of a lunatic asylum become, if they were not before, both afflicting and unsalutary.'"

In several other places the author recurs to this subject. "Again and again (he says) I have been the means of preventing the incarceration of fathers, of mothers, of sisters; and these very individuals are now holding prominent places in their respective circles; and were it not manifestly inexpedient so to do, I could point out in many spheres the incalculable advantages I have secured to these individuals, and the obvious social evils I have thus prevented."

The therapeutic measures employed in insanity occupy a prominent place in this part of the volume. The general principles of treatment are first discussed. "Time (the author observes) is of the greatest importance with reference to the treatment of insanity. It is in early cases so much may be done, the chances of cure being in the inverse ratio to the period of duration; and although we are encouraged to persevere from finding that in some few instances persons have been restored to the full use of their mental faculties after five, ten, and even twenty years insanity, yet these cases are but few in number, and must be considered as the exception. Experience seems to justify the conclusion, that if decided improvement does not occur within twelve months after the attack, the chances of recovery become very much diminished, and the younger the patient the greater the chance of cure."

"In the treatment of insanity, it is most essential to refer it to its proper cause, to ascertain if it be dependent on some physical effect, or whether the result of mere error in perception. If, on inspection after the death of a maniac, we find inflammation of the brain or its membranes, effusion, ecchymosis or ramollissement, to a certain extent we may be justified in attributing the insanity to the pathological condition observed; but supposing, on the other hand, no morbid alteration can be detected, yet the symptoms during life may have been equally severe, as in those where disease was so evident, here we must pause ere we attribute the effects to the same causes."

In many recent cases, no alteration in structure can be detected, nothing, in fact, to account for the symptoms; but when insanity has continued many months or years, the membranes are often found thickened, the bones of the cranium indurated, sometimes effusion, and not unfrequently ramollissement or atrophy; this cannot excite surprise when we reflect that of the number of those who die lunatic half are paralytics.

There is almost always extreme irritability in incipient insanity; generally the brain first suffers, then some other organ. The great object, however, is always in the first instance to allay irritation; endeavour to ascertain whether the brain was primarily affected, or whether insanity followed some visceral affection. It is of the greatest importance to determine whether insanity is symptomatic or idiopathic; whether the result of mere error of perception, or whether the medium through which we reason is at fault; whether it has arisen from physical or metaphysical causes. An individual may at once, from some sudden shock, become incapable of perceiving, discriminating, or judging correctly, and it is in such cases, when tranquillity has been restored by narcotics, that the metaphysical treatment has been so successful. If the excitement, consequent upon reaction in these cases, be not speedily lulled, the brain itself often becomes congested or inflamed; and this continuing, symptoms increase, and those alterations in the brain and membranes so frequently observed, more or less speedily occur."

The individual therapeutic agents which are considered separately by the author form a goodly list, and include bleeding, purgatives, diuretics, emetics, opium, morphia, digitalis, hyoscyamus, conium, lactucarium, camphor, belladonna, hydrocyanic acid, colchicum, stramonium, aconite, cannabis indica, lobelia inflata, stimulants, tobacco, anti-periodics, the warm-bath, the semicupium and pediluvium, the ice-cap, the douche, the cold-bath, the cold shower-bath, exercise, music, &c. &c.

The author's remarks upon narcotics, founded as they are on the result of a good deal of experience in the use of this class of remedies in insanity, are deserving of attention. Among the preparations of opium, he gives the preference to the hydrochlorate of morphia.

"If opium be ordered solely as a hypnotic, it should not be in combination with aromatics, as is the case with black-drop; for although this preparation is stronger than laudanum, and decidedly more anodyne, yet its narcotic power is considerably diminished, while its stimulating effects are augmented. Rousseau's laudanum is stated to be rendered much milder than laudanum or opium, by the fermentation it undergoes. . . . The liquor opii sedativus is undoubtedly much milder in its effect, and less stimulant, than laudanum; and many years since I made it the subject of experiment, in order personally to determine as to its efficacy, and I found it more uniform and certain in its effect, while it did not cause the disagreeable waking symptoms so often noticed when an opiate has been given. Many persons who slept well with it, passed a restless and uncomfortable night when laudanum was substituted for it. Battley's solution has been of the greatest service, and I believe it to be surpassed by no preparation except the hydrochlorate of morphia."

Dr. Williams's object in this publication has been, he tells us, "to render it an essentially practical volume, that may be at once consulted by the medical man when called to the responsible duty of treating such difficult cases." We think he has been successful, and that he has supplied a deficiency which has long existed in this department; and we have little doubt that the volume will meet with the same favourable reception from the profession as the former.

#### OBSERVATIONS ON THE SANITARY INSTITUTIONS OF THE HEBREWS AS BEARING UPON MODERN SANITARY REGULATIONS.

By the Rev. ABRAHAM DE SOLA,  
Lecturer on Hebrew Language and Literature in the  
University of McGill College, Montreal.

ONE of the strangest of all moral phenomena in the present day is, perhaps, presented in the trifling, nay, almost imperceptible, effects which the experience and teachings of ages have had in the legislative enactments and individual efforts of modern nations with reference to the all-important subject of health. Strange also is the fact, that although the principle of self-preservation, even in itself, should naturally incite communities, as well as individuals, to endeavour to profit by, and to act upon, teachings, always plentifully attainable if duly sought, yet by a most culpable negligence and apathy, more especially visible in large cities, have miasma and plague, malaria and consumption,

been permitted to generate, and death to run riot, amongst those who, but for the carelessness and cupidity of their fellow-men, might have attained an age almost reaching that of the patriarchs of old. Such procedure must not only be highly condemnable in the eyes of man, but necessarily sinful in the sight of God. For as is His wont, the all-merciful and all-wise CREATOR has not left us without guidance in a matter which, next to the due care and health of our souls, it is most necessary for us to know. Thus it never has been, as indeed it never can be, questioned, that the most ancient, and at the same time most sacred treatises on the subject of a national and individual hygiene—the legislation of Moses son of Amram—contains the wisest and most valuable principles, recommendations, and enactments on the subject of health, which, though thousands of years have elapsed since their enunciation, do yet remain like “all which proceedeth out of the mouth of the Eternal,” just as valuable and just as wise as when first revealed for the edification of the Hebrew people, and are therefore, now, as then, fully worthy our most attentive and reverent consideration.

Among the Hebrews, who, under God, have preserved these enactments to the present day, it has ever been a golden maxim, “there are no riches can compare with health;” and this principle is equally developed in their post biblical, as well as in their biblical jurisprudence, as it will be our endeavour to show in this pages. The maxim appears also to have been in no small degree appreciated and acted upon by the ancient heathen nations, for as we all know, their legislators not only passed laws calculated to secure an athletic, healthy race of men, who would best serve their respective states, but also for the healthfulness of these states themselves; and their orators and poets, as is also well known, frequently called the attention of the people to the subject, in order that, being reminded in the words of Virgil,

Noctes atque dies patet atri janua Ditis,  
Sed revocare gradum, superasque evadere ad auras,  
Hoc opus, hic labor est.\*

they might thereby accord an universal and cheerful obedience to the laws; and even with respect to Christian nations, it is a question which, we think, cannot be so immediately decided in the affirmative, whether, in the first century of Christianity, they were less appreciative, than their descendants are, in the nineteenth, of the truth conveyed in the saying of the old English moralists, that “there is but one way of coming into the world but a thousand to go out of it,” or whether they could parallel the atrocities which are daily revealed to us with reference to the impurity and adulteration of food, the state of city graveyards, the noxious manufacturing processes carried on in densely populated neighbourhoods, and a thousand other evils calculated to undermine the public health. These, however, are questions we do not attempt to decide, but leaving them for the consideration of others more competent to do so, we proceed to examine that branch of the general topic which we have selected as our own, and will endeavour to show what are the ideas and practice of that people to whom a code of sanitary laws was first revealed.

But it is proper to premise, that the sanitary institutions of the Hebrews are not to be looked for in the Bible only, though the grand principles upon which they are based have undoubtedly been borrowed by them from, and credited by them to, the sacred volume. It is to that vast repertory of the national traditions, that well-known, but little understood compilation, the Talmud, and to their later casuists, that we must turn, would we find and correctly estimate the multifarious, important, and highly interesting sanitary constitutions of a people who honoured these constitutions with a most scrupulous observance, not merely because they regarded them as mere matters of expediency, utility, or profit, but as the strict, unavoidable, and uncompromising requirements of their heaven-born religion.

The pains and penalties following dereliction or neglect—in some cases amounting to excision—also tended, both in biblical and post biblical times, to secure from the Hebrews a scrupulous observance of their sanitary laws. We are well aware that some few, writing in an unfriendly spirit of the book in which they are contained, have condemned them as overloading man with useless ceremonies, which enter into every hour of his existence and make him the mere creature of ablutions and precautions. But it is very evident, that this objection must be pronounced quite futile, until it can be shown that a careful and strict attention to the promotion of health is at all condemnable, pernicious, or unwise. By another class a further objection has been made to them, that although their tendency may be good, yet is the minuteness of detail employed in the books of Hebrew jurisprudence highly objectionable, and not to be tolerated in the present refined state of society. But here it is also evident, that such an objection is utterly groundless, and could only be adduced but for a sinister purpose. For if they become objectionable and intolerable on this account then equally objectionable and intolerable must we pronounce every medical book, tract, or treatise, from the days of Galen downwards, since it needs no very extensive knowledge of both classes of authors to decide that the former are clearly and indisputably more measured in their *modus scribendi* than the latter, notwithstanding which but few would recommend the suppression of valuable medical treatises on this account. The truth is, that, equally with any modern casuistic or scientific writers, the Jewish Doctors or Rabbis wrote for intelligent, considerate, truth-seeking men. They wrote neither for children, for fools, nor for blind zealots: and when they entered into details designed to promote the bodily, and consequently the mental, health of their people, they knew that they addressed men who would only consider themselves “a wise and discerning people” accordingly as they respected the “statutes and judgments so righteous,” upon which their teachers amplified—men who, whatever their faults otherwise, could yet duly appreciate recommendations to purity, chastity, and sobriety, and could not only ostensibly, but actually and in reality, act up to them—men whose cheeks would not mantle with the deceitful hues of a false modesty when particularization of wholesome, sanitary, and moral laws were addressed to them in public; while in private, they would, with brazen brow and unblushing face, outrage every one of these laws, and yet loudly proclaim a refined state of society, as, perhaps, is but too much the case in our day; and that the Hebrew sanitary institutions, despite their minuteness of detail, have proved to the nation neither hurtful to body nor baneful to mind, is, we think, evident from various considerations. In the first place, although there flows in the veins of the Hebrews the blood of the most ancient nation remaining on earth—the same blood which once animated Abraham, Moses, David, and Isaiah,—although the stake has destroyed of them its thousands, and the sword its tens of thousands—although monarchs and legislators, from the days of Pharaoh downwards, have passed enactments for their extermination, forbidding, as is the case even in the present day, their obedience to one of the first laws of Nature—although found in every country and clime, amidst the snows and ice of a northern, and the burning sun of a southern latitude,—and at all periods of their history, subject to a thousand adverse and destructive influences, yet do they remain a wonderful living problem, the same *undeteriorated* indestructible race, with the same characteristics every where traceable amongst them, with an eye not less bright than when it was called to witness the lightnings of Sinai’s mount, and with a step not less elastic then when it repaired to the Holy Temple which God vouchsafed to make the place of His especial residence; in short, with the same favourable, energetic, and high organization among the men, and with the same instances of rare beauty among the women. Nor do we find them, in consequence of their sanitary regulations, more subject to diseases, or obnoxious to epidemics of all descriptions, but the contrary; for it is undeniable that the mass of the nation, who are duly observant of their dietary laws, are re-

\* Æneid lib. vi. (127.) Thus rendered by Davidson, “Grim Pluto’s gate stands open night and day; but to reascend from there to the upper regions, this is a work, this a task indeed.”

markedly free from certain classes of diseases, particularly those of the skin and the hypochondriac regions; while ever since attention has been given to the statistics of epidemics, both in Europe and America, it has been announced as an extraordinary fact, especially during the ravages of Asiatic cholera, that proportionably the Jewish community have remained in a remarkable degree unscathed under those awful visitations.

(To be continued.)

DUBLIN: WEDNESDAY, JUNE 30, 1852.

### OPERATION OF THE DISPENSARY ACT.

Now that the working properties of this piece of legislative machinery have been pretty well tested, and that our friends in the train which it draws are fairly started on their journey, we may venture from time to time to point out its perfections and defects. With this view, we copy the following article from a provincial journal (the *Dundalk Democrat*), which throws some light on the subject, at the same time refraining from any adoption of phrase or comment in it which may have a personal application, not being in any way cognizant of the local bearings of the question. All we require in such case is, so much evidence, even *ex parte*, as will justify inquiry and suggest any corrections which a view, *primâ facie*, may demand. As there must be much similar cause of complaint arising from the collision of conflicting interests over the country, we venture on the subject with some reluctance, apprehensive that in touching upon local differences we may get entangled in disputes we cannot comprehend. We give the extract to our readers as an illustration:—

Allow me to call your attention to a recent sample of a system rather prevalent in the disposal of public offices in and about the borough of Drogheda, to which your own trenchant and powerful pen has occasionally attracted the notice of your readers.

In the Drogheda Union there was lately a re-division of the dispensary districts, and a re-appointment of medical officers to attend them. The appointments to which I solicit your attention are those made in the dispensaries of Duleek, St. Mary's, Drogheda, Julianstown, and Stamullen.

Dr. Delahoyde of Duleek, was, in the first instance, transferred to St. Mary's district, Drogheda. To this appointment, separately considered, there could be no reasonable objection. A skilful and accomplished practitioner has been removed to a district where his services will be invaluable to a poor and unhealthy population. His position and prospects have been improved, and I heartily wish him every success.

On Dr. Delahoyde's appointment, the village of Duleek, and the poor and extensive district surrounding it, came to be provided for. For many years it had been the residence of a skilful physician. The old ineffective dispensary system had at least provided this much for the relief of the sick poor; and it might be naturally expected that under the new regime their wants would be even more sedulously attended to. So thought the inhabitants of the village; but so thought not a certain influential and eclectic clique, who, I need hardly tell you, have much voice and many votes in such matters, which they invariably exercise with a disinterested impartiality, of which you and the people of Drogheda are perfectly well aware. So satisfied were they and their friends with the energetic, and the actively profound and unvalued medical skill of their cousin, Dr. Darby of Drogheda that, in the plenitude of their public zeal, they secured the appointment for him. Now, the dispensary district of Duleek is fully eleven miles in length, and the village of Duleek is four miles from Drogheda, where Dr. Darby resides. Dr. Darby, it is moreover alleged, was hardly eligible to the appointment at all, not having been a dispensary attendant hitherto. Taking this view of the case, the inhabitants of Duleek have memorialized the Poor-law Commissioners to in-

sist that the appointment should at least be made a resident one. You know how absurd this is of the Duleek people! Is it not absurd to conceive that a man might bleed to death or die of the cholera (God keep it in its native Deccan) while a messenger would be going to Drogheda from any one remote point of the eleven miles, and hunting out Dr. Darby among his patients, and bring him out to Duleek, and then going back for the physick, and then returning again!

Besides, you are of course aware that centralization is now the order of the day. The distinguished clique which I allude to are only applying the same principle to Drogheda which their friend, our late lamented representative, Sir W. Somerville, exercised on a wider scale. They conceived that all the dispensary doctors of the union should reside in Drogheda; and you know they will have their own way.

Just let me cite you another case in point:—

I am afraid that this case really requires to be pulled up. It is to the best of my belief a specimen of the "job absolute." Before the new alterations, the dispensary of Stamullen was for many years attended by Dr. O'Reilly of Balbriggan—an active, attentive, and experienced physician, whose duties were exclusively limited to his dispensary and his private practice; and whose services as a dispensary officer were so efficient that the Hon. Edward Preston declared in the Drogheda Board of Guardians that the Stamullen dispensary was one of the best administered in the kingdom. This fact, and Dr. O'Reilly's long connexion with the district should, as a mere matter of course, one might suppose, have secured his election.

But neither one consideration nor the other, though each involved human life, and implied human sickness and suffering, was regarded. Even before the election occurred, I have heard Dr. O'Reilly was informed, plainly and distinctly by one of the committee, that there was no use in his standing; that the committee had been empanelled with quite another purpose. That purpose they secured by the election of Dr. Kelly of Drogheda to the united districts of Julianstown and Stamullen; and all this was done on the plain principle of log-rolling. If Dr. Kelly had not been appointed to Stamullen, Dr. Delahoyde would not have got St. Mary's, nor Dr. Darby have been nominated to Duleek! Do you mind?

Now, Dr. Kelly is a bit of a medical pluralist; he attends the workhouse for a salary of eighty pounds a year (recently raised to that figure in consequence of the overwhelming and unremitting nature of the duties, which he alleged left him hardly any time for private practice); he attends the fever hospital, a tolerably laborious office also, with its average from thirty to forty cases. He attends the military barracks, and he has very extensive private practice in Drogheda.

Do you think it is possible that any medical man can give effective attendance to an extensive dispensary district, poor, populous, and many miles distant from Drogheda, in addition to duties so urgent, so incessant, so responsible, so lucrative? I don't think it. I think a man should pay his visits with a special express steam engine, and write his prescriptions with an electric telegraph to do it; and I think there would be lives lost, and much unnecessary human suffering occasioned by the transaction nevertheless. Imagine a poor man from Clonavey, with his wife or child lying ill in the fever, or the cholera, or any other disease, needing instant and vigilant attendance; imagine him walking the long ten miles to Drogheda, tracking Dr. Kelly from the workhouse to the barracks, and from the barracks to the fever hospital, and from the fever hospital to house after house through the town, or perchance out to Collon, or on to Bettystown, or to this or the other country gentleman's seat; and so imagine all the delay and all the ordinary and extraordinary difficulties of getting the medical attendant of Stamullen to his own proper post, while a suddenly-stricken patient lies unrelieved, dying, perhaps dead. Imagine this occurring, not by accident, but by system; not once, not twice, but every week, and every day perhaps; and the oftener precisely in proportion to the extent of the claims upon his services elsewhere, as in times of epidemic, or of other generally prevalent sickness.

This is emphatically a question of life and death. I am convinced that if it was brought in all its bearings and contingencies under the notice of the Medical Commissioners of the Relief Act—I am satisfied that if there was an exact investigation into the circumstances and requirements of the district, that, in justice to the afflicted, some other arrangement should be forthwith adopted. I ask, at all events, to lift the curtain of the press, and let in the light of public opinion upon it.

MEDICAL LIFE IN LONDON.

(Continued from page 367.)

London, June 19, 1852.

At Bartholomew's Hospital everything is represented by a staid and respectable mediocrity. With a magnificent income, and opportunities of wide and enlarged practice only second to Guy's, it has not done as brilliant things as the Borough hospitals. A little fortune has just been thrown away taking down a very good front and putting up a very ugly one; external appearances go a good way with our friends of St. Sepulchre's, and yet the fine old front, and a set of arches, under shadow of which the ghost of Rahere and Mr. Stanley's carriage seemed to enjoy a divided empire, like Jupiter and Cæsar, are now universally regretted. The wards of Bartholomew's, especially the new ones, are very fine—Mr. Lawrence and Mr. Stanley the presiding spirits.

Bartholomew's has 600 beds; Mr. Stanley is a great favourite with everybody, from the pupils and nurses down to the military gentleman at the gate who spends the latter part of a battlesome life selling bottles to the out-patients at a penny a piece.

Stanley is chiefly known by his beautiful book on "Diseases of the Bones;" and going round "Rahere" and other wards exhibits some of those little peculiarities that remind you of old Roux at the Hôtel Dieu, and O'Beirne, so great in Dublin, on the "Rectum." As an examiner at the college his manner is very good. Latterly, his brougham and pair is to be seen very busily, night and day, down Oxford-street and Holborn to Bartholomew's. In some of the schools we have special points on which the lecturers plume themselves; at St. George's, the peculiar views on the nerves of the uterus, by Dr. Robert Lee, which, by the way, Dr. Snow Beck has taken the liberty of offering objections to; at the London University, Kiernan and his researches on the liver; in the Borough, Sir Astley Cooper and poor Aston Key are the theme of every discourse; at St. Thomas's, Cheselden operated times without number for stone; but at Bartholomew's, we cannot call to mind anything very striking. Mr. McWhinnie, it is true, lectures on comparative anatomy; but it does not appear that he has yet surpassed Oken or Owen. Mr. Paget and Mr. Holmes Coote, and some of the younger men, are perhaps exceptions; but it requires little knowledge of London cliquism to discover that our younger men at Bartholomew's, like those all over London, have ancient Sysiphus to envy; while the old men, here and elsewhere, with money, and good dinners for the "gentlemen of the press," may vend their inanities all over the town. The most brilliant discovery of the younger men is sure to be laughed at. The speculum in uterine diseases, compression in aneurism, Marshall Hall's discoveries, and many other things, are only slowly emerging from this heap of ridicule thrown on them. If the anæsthetic effects of chloroform or ether were discovered in London, nothing under heaven could have saved them from falling into oblivion; and when one thinks of John Hunter dying heartbroken from the jealousies of London practice, Syme collecting his traps and running away from them, Jenner (Dr. Oliver Goldsmith, as he is called), and many others, one would wish for some person like Mr. Bozthorn in "Bleak House," who threatens to demolish the Admiralty for their treatment of the navy assistant-surgeons, to demolish also the abuses that infest the profession itself. The Medical Societies in London, especially the Medico-Chirurgical and Epidemiological, may bear comparison with any cognate societies in the world. Little jealousies, of course, there are evinced now and again in the discussion of papers; but in point of usefulness and advancement, they exhibit a singular contrast to the trading of the small practitioner. This may not have much to do with Bartholomew's Hospital, except to place in clearer light the fact, that while Mr. Paget and Mr. Holmes Coote, and men of that class, may be filling the sieve of the Danaides, giving admirable lectures and bringing abstract theoretic doctrines to bear on practice, bitter-ale statistics at the other end, and the little peddling chemist in his brougham and counter-practice, are more supported by the journals. The man of tooth-brushes and Godfrey's Cordial, with the stylish homœopath from Mount-street or Grovesnor-square, meet in Rotten-row and Hyde Park; the tuft-hunting of Dr. Paris and the College of Physicians—an amiable weakness of an-

other kind—also covers a great amount of shamming. The quiet honest workers, Carpenter, Paget, Simon, Owen, almost unknown, except to be abused and criticised.

Mr. Lawrence is the senior lion at St. Bartholomew's. In somewhat enlivening contrast to the melancholy trading we have alluded to, may be mentioned the high professional character of this eminent surgeon. Few men are so respected in London. The pupils at Bartholomew's are a wild rakish set enough, but Mr. Lawrence's *in loco parentis* style of managing them has the happiest effect. At Ealing Park, Mr. Lawrence entertains like a king, and the industrious pupils know it. Mrs. Lawrence's garden and collection of flowers is perhaps the finest in England.

Mr. Paget has just finished a highly instructive course of lectures in the college library on malignant tumours, the preparations and drawings chiefly taken from patients in Bartholomew's. A very great change of opinion has taken place recently as to the propriety of removing cancerous and other malignant growths. The sad array of cases where cancer returned after operation, was sufficient to shake the faith of the most obstinate advocate for the knife. Mr. Simon of St. Thomas's, one of the ablest men in London, and Mr. Paget, seem both of opinion that where secondary deposits of cancer occur, epithelial or otherwise, operation is inadmissible. Extreme pain or very great risk of life immediately, from the situation of the disease, may make operations a subject for discussion; but in the vast majority of cases we must unlearn much of our former dicta on this subject.

Mr. Paget's manner of lecturing has all the force of a written essay; the college lecture-room being at present in "bricks and mortar," the spacious library was quite filled with the chief men in London, and many from the provinces, on whom the views of this eminent surgeon and microscopist seemed to make a very great impression. With the exception of desquamative cancer—some singular cases of which have been noticed in Dublin by Dr. Jacob, I think—he seemed to say that operations are all measures for exceptional adoption. Many of our medical leaders and essays in London never were read, never could be read, and it is confidently believed never will be read; but Mr. Paget's essays and lectures do not belong to this category. His intimate knowledge of the continental museums, of the writings of Rokitsansky, of Köeliker, the other day in town, all mark him out as the best opinion on the subject in England.

One of those miserably small cases of malpraxis that will now and again occur, has just happened at Norwich. As the *corpus delicti* is many miles from London, and the subject a homœopath, we have much virtuous indignation; while in London itself, at any of the hospitals, patients are to be found who can tell similar stories. In London, homœopathy is quite *un autre chose*, and homœopaths, as they are the fashion, like mediæval curates of the Puseyite school, are met in consultation and received with open arms. The abortive attempt in the House of Commons to exempt medical men from the pleasantries of the Militia Bill, is also much talked of, and is only another instance of the want of moral influence in our periodical literature, especially of the hebdomadal kind. Many of the students in the Borough hospitals, just looking out for their summer "grinding class," have now visions of bayonets and pipeclay not at all agreeable. The universities, of course, have been exempted, but the thousands of "advice gratis" men in London have been entirely disregarded. The *prestige* or moral weight of the mass of the profession is felt every day to be less and less: as a trade, it must take its place with all others. In searching out the causes of quackery in England, especially of hydropathy, homœopathy, &c., it is painfully evident to all thinking men that this want of pure professional feeling is at the bottom of it. It is a weekly tune of "tweedle-dum and tweedle-dee" between the journals. Whatever will not "sell," like Peter Pindar's razors, is strictly prohibited, and men who suit the market, like the string of worthies we often see in solemn train in Fleet-street with placards on their shoulders, are always before the medical eye on paper.

The navy assistant-surgeons are also in point; but does any honest man believe we have any one to thank but ourselves for the slight sought to be thrown on this department of the public service? A dispensary surgeon, educated in Ireland, with the manners and habits of a gentleman, dines with the lord or earl: the navy surgeon is good enough for the midshipmen. One man looks on his calling as a profession, and is respected; the other has the misfortune to be the victim of the trading principle, where so much disease is so much raw material; and trading journals assist the biggest

purse. Our books on "homœopathy and homœopaths" begin at the wrong end. The homœopaths, to a man, are persons sick of the old trade, but without moral feeling to resist the temptation to quackery, and without any tie as regards the best possible instructors, the weekly journals, which they look on as "leather and prunello."

Mr. Lloyd at Bartholomew's is an excellent practical surgeon, much liked by the pupils. Mr. Skey and Mr. Paget are two very superior surgeons also. Mr. Skey's book is a reflex of his practice: it has caused some jealousy. He should have asked permission of the journals and their critics before he set about anything so original.

In the practice of physic department, perhaps, Bartholomew's has made no sign with Tweedie, Watson, Bright, Copland, &c., in less pretending hospitals. We cannot say much for Roupell, Hue, or Burrows; a very general and unpretending mediocrity reigning more in this part of Bartholomew's than in the surgical division. Dr. West is more favourably known in his department.

#### EDINBURGH COMMENTS ON LONDON SURGERY.

WE copy the following without expressing an opinion *pro* or *con* on the merits of the question, because we consider a little wholesome castigation, whether merited or not, likely to operate beneficially on large communities liable to form false estimates of their perfections because of their numerical superiority. The Surgeons of London will be nothing the worse of an occasional poke from Scotland or Ireland, now that all are so harmoniously disposed at home. We never yet knew good to come of a calm in the ocean of the medical world; it is but a proof of languor, and portends nothing but apathy and rest. Not that we would applaud a wanton breach of professional peace, or a spiteful criticism of the proceedings of individuals; but only so much challenge as will remind those who rely too much on their position, that there are Surgeons beyond the region to which the sound of Bow Bells reaches:—

##### EXTRAORDINARY DISCLOSURES.

The London medical journals have long and perseveringly accused us of "personality" in regard to our surgical brethren of their metropolis; and upon one occasion we certainly were guilty of it. This was when an attempt had been made to foist upon us, as a new and profitable improvement, the rejected absurdity of proposing to remedy incurable disease of the hip-joint by cutting out a part of the bones affected. As the gentleman who was most active in advocating this procedure represented himself as recently house-surgeon of the hospital where he had witnessed its performance, we expressed our fears that his experience would not realize the sanguine expectations of youth. Instantly there arose a howl of complaint—as when the petulant yelp of some junior in a kennel is caught up by all the pack—which has ever since been prolonged and reiterated in every discordant note of senseless rage. To our readers we may appeal for confirmation of the fact, that there never has been afforded by us any other pretext which admitted of being twisted into a ground for the charge of personality. It is true that we have not hesitated to express our sentiments in regard to published facts and opinions, and have not been deterred from stating what we believed to be the truth by the position or character of the authors whose works have been submitted to our judgment. If unsound pathology, bad practice, and results worthy of such foundations, have elicited condemnation on just grounds, it is plain that the blame should not rest upon us. But it really seems as if the true nature of various doctrines communicated to the profession were not perceived until reflected from our northern mirror; and that thus the odium of the folly or mischief exposed is attributed to us. For instance, if we had said that puncturing the bladder from inability to pass the catheter was so frequent in London that one surgeon of an hospital could produce forty cases of its performance, "twenty-four of them being in his own practice;" or that another gentleman, who had been professor of surgery in both University and King's College, maintained that attempting to force the catheter through a stricture was justifiable and safe, "when properly performed;" "what he wished to convey by the operation being properly performed was this, that if, upon trying to urge the catheter, the urethra itself should give way, and be per-

forated, then that the proceeding should be abandoned;" or that this same surgeon, in a private case, did attempt to force a catheter through the stricture until "the urethra gave way," then cut into the perineum in search of the canal, but without the "urethra being struck," and lastly punctured the bladder from the rectum; or that the same gentleman had "twice witnessed, in the hands of a very able surgeon, the bladder missed in the attempt to puncture it above the pubes;" or if we had alleged that many surgeons in London seemed to think having occasion to puncture the bladder five or six times in the course of their practice no subject of shame or reproach, then, indeed, we might have been charged with calumny of the deepest dye. But it appears that upon the evening of the 13th of April last, all that has been said, and a great deal more to the same effect, was publicly stated at a meeting of the Royal Medico-Chirurgical Society, and has been unscrupulously exposed to professional comment by the very journals which accuse us of hostility to our brethren of London.—*Edinburgh Monthly Jour.*

#### CASE OF RETENTION OF URINE.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—You will oblige me by inserting in your next number the accompanying letter. It is the only reply I will feel called on to make to the criticisms of Dr. Little on a "Case of Retention of Urine," reported by me in your journal of the 9th of May.—I am, dear sir, yours truly,  
Sligo, June 18, 1852. ROBERT LYNN.

DEAR A. B.,—You are aware that Dr. Little and I have not *spoken* since our quarrel about Mr. M——, six months ago; you also know something of the state of practice in Sligo: you can, therefore, form an opinion of the *ethics* of Dr. Little's attack on me in the *MEDICAL PRESS* of June 9th, and of the *good taste* towards his medical brethren, and the correctness of his assertion, "that the great majority of such cases pass through my hands," &c. I do not feel it necessary to enter into any defence of my treatment of that case. I will be satisfied with stating that during its progress I had the approval of medical brethren on whose judgment and professional honour I place the fullest reliance. That the treatment of the case was eminently successful (the patient being now in excellent health); that it was truthfully reported; and moreover, that it was one of four cases of retention of urine in private practice which I had under treatment about the same time: all of which went on favourably, without the "cooperation" of Dr. Little being deemed necessary.

If you have read the recent numbers of the *Medical Times*, you will have seen that the word "tunnelling" was used by Fergusson of London (no mean authority), who is an advocate for forcing a passage, in certain cases of obstruction of the urethra, when the surgeon has sufficient confidence in himself.

In my report, it was distinctly stated that the patient obstinately refused to submit to any other operative proceeding than that which I adopted, and which turned out so remarkably successful. Even if I had been so inclined, I fear I would not have procured the sanction of my brethren for the course pointed out by Dr. Little—namely, "practising the deception of tapping the bladder from the rectum, *without consulting my patient's wishes, or at all informing him of what I was about to do.*" I do not intend allowing myself to be forced into any correspondence on this subject. You know I have neither time nor inclination for controversial letter-writing.—I am very truly yours,  
Sligo, June 12, 1852. ROBERT LYNN.

We regret exceedingly that we have inadvertently been the cause of any public manifestation of difference of opinion between two members of our profession whom we respect. In Dublin we have no great objection to allow contending parties to "fight it out" in our columns; but in places of which we have not much local knowledge, we find it necessary to be more cautious. Lately, in the simplicity of our hearts, and as a mere matter of course, we were so unlucky as to give insertion to an abstract of some proceedings of the Cork Surgical Society, which, in the twinkling of an eye, brought an old house about our ears before we knew that we had stepped within its threshold.

From Ennis we were obliged to beat a hasty retreat, leaving our previous supporters to fight it out after the fashion of the Kilkenny cats; and in other places we have had to make the best compromise we could. So we pray our friends in future to respect our neutrality with as much forbearance as they can afford.

### EXPERIMENT IN THE LEECH TRADE.

THE following announcement is gratifying. A better supply of this valuable medical "appliance," as the poor-law people would call it, is much required. The success of the attempt is, we hope, certain, seeing that the animal is indigenous here. Can any one tell whether it is still found and supplied from ponds in the county Kilkenny?—

A LEECH CROP.—Mr. McIntosh, the intelligent steward of George LeHunte of Artramont, Esq., has just communicated to us the following novel fact:—Lord Desart lately set a piece of marsh of about forty acres, on his estate near Callan, to a company of Frenchmen, who immediately fenced it in; and having freely irrigated it from an adjoining stream, proceeded to sow it down under a leech crop—yes, startle not, gentle reader—a *living leech crop*. "The seed," if we may so express it, was contained in sacks, each sack holding 15,000 leeches, which were scattered from the hand, just as corn is sown. What will be said to this new race of Gallo-Irish Bloodsuckers!—*Wexford Independent*.

### ADDRESS TO DR. PERCEVAL OF STRADBALLY.

WE, Subscribers to the late Stradbally and Luggacurren Dispensary, and inhabitants of the district, cannot permit our connexion with you to cease without recording the sense we entertain of the very efficient manner in which you have discharged its various duties—the diligence and regularity with which you conducted the ordinary business of those institutions—the readiness with which, regardless of personal convenience, you answered every call of suffering and distress—the unwearied attention and the anxious kindness which you bestowed on cases of protracted illness, have deservedly acquired for you the respect and esteem of all classes.

While we pay this willing tribute to your public services, permit us to add, that the same qualities which render these so valuable, carried, as they are, into the more private relations of life, have tended in no common measure to increase our feelings of regard and affection.

We are confident that in your new position under the recent Medical Charities Act, the same zeal and professional skill will be continued, and we rejoice to think that you are still to remain among us as physician and friend.

Accept, dear sir, the accompanying tribute of our sincere regard and esteem, and believe us your faithful friends.

[Here follow the names of the subscribers, including those of the most influential gentry in the vicinity.]

Now ready, 18mo, 510 pages, bound in roan, price 6s. 6d.,  
**THE PRESCRIBER'S COMPLETE HANDBOOK:**  
Comprising the Principles of the Art of Prescribing; a Materia Medica, containing all the principal Medicines employed, classified according to their Natural Families, with their Properties, Preparations, and Uses; and a Concise Sketch of Toxicology.

By TROUSSEAU and REVELL.

Edited, with Notes, by J. BIRKBECK NEVINS, M.D.

LECTURES on HISTOLOGY, delivered at the Royal College of Surgeons, England. By JOHN QUEKETT, Author of "A Practical Treatise on the Microscope." 8vo, with 159 Woodcuts, 10s. 6d.

### LOUTH MEDICAL ASSOCIATION.

At a Meeting of Medical Men held at Dundalk, on the 4th of June, 1852,

JOHN TRIMBLE, Esq., M.D., in the chair,

(Present: John Brown, William Pollock, John Neary, and Richard Montgomery, Esqrs.,)

Letters were read from Doctors Massey and Darby, regretting their inability to attend, and approving of the object of the meeting.

The following resolutions were unanimously adopted:—

1. That feeling the necessity of union among the members of the Medical Profession, we form ourselves into a body, to be styled "The Louth Medical Association."

2. That the object of this Association shall be to promote the interests of the Profession generally, and to advance the object of Medical Science.

3. That we consider this Association as a preliminary step to the formation of a Provincial Association, the advantages of which to Medical Science have been so apparent in the sister kingdom.

4. That all duly qualified Physicians and Surgeons are eligible to become Members of this Association.

5. That our next meeting for the more perfect organization of this Association shall take place in Dundalk, on Thursday, 1st July next, at Two o'clock p.m., and that our Secretary be requested to send copies of these resolutions to every duly qualified Medical Practitioner in this county.

6. That we cannot separate, without expressing our opinion that, even from the limited experience we have had, we deem it our pleasing duty to express our perfect confidence in the Commissioners of Medical Charities and the Medical Inspectors.

JOHN TRIMBLE, M.D.

Dr. John Trimble having left the chair, and Dr. Brown being called thereto, the thanks of the Meeting were unanimously given to Dr. Trimble for his dignified conduct in the chair.

JOHN BROWNE, M.D.

RICHARD MONTGOMERY, M.D., Sec.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

### THE COMPOUNDING DEPARTMENT AT

### G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

On July the 1st, No. XIX., price Six Shillings,

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

 Change of Proprietorship.

BEWLEY, OWEN, AND CO., APOTHECARIES,  
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING  
OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

\*\* GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

THE Examination of Candidates for the Degree of M.D. will be commenced on Monday, the 2nd of August, and continued daily, till finished; immediately after which the Graduation will take place. Those intending to become Candidates are requested to forward the necessary documents, on or before Thursday, the 22nd of July, to the Professor of Medicine.

REGULATIONS.

Practitioners who possess a Licence or Diploma from any of the Royal Colleges of Physicians or Surgeons, or from the Apothecaries' Company, and who have been engaged for at least five years in the practice of Medicine, will be admitted to examination on producing their Licence or Diploma, along with satisfactory evidence of good moral character, and of having studied the Classics at a University or at an Academy of acknowledged reputation.

Practitioners who commenced their Medical Studies before October, 1840, and who have not been in practice for five years, will be admitted to examination on producing, along with their Diploma, evidence of attendance at the Classics, of good moral character, and of having been engaged in the Study of Medicine for four years, during which they must have attended, in some recognized School of Medicine, the following courses of Lectures:—

SIX MONTHS' COURSES.

Anatomy	...	...	...	Two courses.
Chemistry	...	...	...	One course.
Materia Medica	...	...	...	One course.
Surgery	...	...	...	One course.
Institutes of Medicine and Physiology,	...	...	...	One course.
Practice of Medicine	...	...	...	One course.
Midwifery	...	...	...	One course.

THREE MONTHS' COURSES.

Dissections	...	...	...	Two courses.
Practical Chemistry	...	...	...	One course.
Medical Jurisprudence	...	...	...	One course.
Clinical Surgery	...	...	...	One course.
Botany	...	...	...	One course.
Clinical Medicine	...	...	...	Two courses.

In addition to the above, every Candidate must have attended for two years the Wards of an Hospital containing one hundred beds, and during three months a Shop or Dispensary for the compounding of Medicines.

\*\* The University and King's College is the only Institution in Aberdeen which has a legal power of granting Degrees in Medicine. All Medical Diplomas purporting to be from the University of Aberdeen, not promoted by the Professor of Medicine, and not signed by the Principal and Professors of King's College, as given below, are illegal and void.

#### CASE OF LITHOTOMY.

By Professor HARGRAVE.

(Reported by Mr. Edward H. Sargent.)

R. W—, ætat. 42, bricklayer, of good general health, intemperate, admitted November 29, 1851, into the City of Dublin Hospital. He states that about twenty-five years hence, he fell from a house on his back, and received a severe shock, followed by pain in the epigastric region.

About six years ago he was seized with pain and heat in the scrotum, and passed three stones, like small peas. Twelve months ago he began to experience difficulty and pain in expelling the last drops of urine, and applied to Mr. Tufnell. About the same time he began to have need of frequent micturition. Last June he perceived a ropy kind of mucous deposit in his urine, and felt great itching pain in the glans penis.

When he turns from one side to the other, he feels a scalding sensation in the bladder. Posture has no effect with regard to pain; he lies chiefly on his back; there is a large amount of mucus in his urine, which is neutral; he has always suffered from obstinate constipation. Both on admission and repeatedly afterwards, the sound was introduced into the bladder, but no stone could be detected.

He was treated with buchu, uva ursi, cubebs, muriatic acid, and acid injections of the bladder, until December 24th, when, the mucus having disappeared, he was discharged.

In January the mucus began to return, and on the 20th, on introducing the sound, a calculus was distinctly felt. For some days, he stated, he has perceived the stone rolling about. He was then readmitted. Next day he said the stone was fixed and did not roll about as before. He was now treated with inf. krameriæ and muriatic acid, the urine being slightly alkaline.

February 8, 1852: The mucus having greatly diminished, the lithotrite was introduced, and the calculus seized;

VOL XXVIII.

only a small detritus, however, came away. There was only a slight irritation caused by this attempt. 10th: The lithotrite was again introduced and the calculus seized and partly crushed. About ten grains of it came away in the urine on the three following days; there was more irritation after this attempt than after the first. 17th: An attempt was made to-day but failed, the bladder having become very irritable. It was deemed inexpedient to persevere with lithotripsy, and lithotomy was resolved upon. March 4th, eleven a.m.: The patient was now placed on the table, and having inhaled chloroform, the lateral operation was proceeded with. The perineum was very deep. The calculus was then removed, being very rough on one side, weighing 5ii. gr. xii. On being removed to bed, he complained of great pain, and got tinct. opii gtts. xl. Pulse 84, fair and regular. One p.m.: Has suffered intense agony for the last hour; fainted once; very little hæmorrhage; urine passing freely through the wound, mixed with blood; on introducing the canula armed with linen, and packing it with charpie, he experienced almost instantaneous relief; urine began to flow through the canula. Ordered tinct. opii gtts. lx. Four p.m.: Has no pain since; pulse fuller, 78; warm and comfortable. Ordered tinct. opii gtts. xx. Eight p.m.: No pain; urine flowing freely through the canula; pulse improving, 74. 5th, eleven a.m.: Quiet night; did not sleep; moderate perspiration; pulse full, soft, 62; no thirst. Five p.m.: Passed a good day. R Mur. morph. gr. ¼. 6th: Good night; canula was now withdrawn after forty-eight hours, and was loose; suppuration commencing. Ordered an oil draught. Five p.m.: 3vi. urine have passed through urethra; pulse 78. 7th: Suppuration healthy; 3vi. urine have passed through the urethra; bowels once moved, freely; pulse 70. 15th: 3viii. urine have passed, with small amount of mucus, neutral; slept for four hours last night. 17th: All the urine now passes through the urethra; urine slightly acid; inferior angle of the wound healing. 20th: Wound healing rapidly; urine strongly acid; no trace of mucus under the use of decoct. Pareiræ. 28th: Still improving; urine acid; suffers from flatu-

lence; inferior angle of wound healed. Decoct. buchu, spt. ammon. aromat. and spt. zingiber, instead of decoct. Pareiræ. 30th: Stomach much better; looks much more healthy; getting colour.

*Observations.*—This case presents one of the examples which enables the surgeon to have the operation of lithotomy in reserve, in case that of lithotripsy cannot be made available for the purpose of relieving the patient of the calculus.

He submitted to three introductions of the lithotrite; in the first, the calculus was seized, and a small portion of calculous detritus was removed; in the second, the calculus was also seized and gave the diameter of half an inch, and so much of it was crushed as to afford ten grains of it being discharged by the urethra; following which attempt there succeeded a great degree of irritation, with increased discharges of vesical mucus; the third trial failed *in toto*, the bladder becoming very irritable during the operation, which irritability increased with a proportionate quantity of mucopurulent discharge mixed with some blood.

The augmentation of the symptoms of vesical irritability and mucous discharge decided me on performing lithotomy.

The patient was placed under the influence of chloroform, five drachms having been administered to him. Nothing unusual occurred during the operation, except that the perineum was much deeper than I anticipated. The calculus was readily seized by keeping the blades of the forceps with their flat surfaces looking upwards and downwards; but a small quantity of blood was lost during the operation, which coagulated rapidly and firmly.

The patient was scarcely well placed in his bed when he began to complain of *intense pain* in the wound, in the rectum, and anus, and some towards the symphysis pubis. He got a draught of forty drops of laudanum. I remained in the hospital about an hour after the operation, and but little, indeed no abatement of the pain. I returned to it in an hour and a half, and was informed that he had fainted from excess of pain, and vomited. His countenance was pallid, pulse small and feeble, and anxiously asked for relief from his sufferings, though he was a man of much firmness of character and well regulated mind. On examining the wound, there was no hæmorrhage to excite any apprehension, the urine flowing freely through it. These symptoms indicated that there was no internal hæmorrhage nor clot in the bladder, which sometimes causes much pain until it is expelled, when all distress ceases. There seemed to be but one source from which this great pain could arise: namely, from the urine flowing over a recent wound, in which there was no contusion or laceration; it was also altered in quality—*i.e.*, being alkaline. With the concurrence of my colleagues, Messrs. Williams and Tufnell, I plugged the wound into the bladder. Before it was completed he began to experience some ease from pain, and expressed himself much relieved. He was given sixty drops of laudanum and replaced in bed. He was visited again at half-past four o'clock, his relief continuing, when twenty more drops of laudanum were administered to him, making 120 drops from eleven o'clock a.m. to half-past four p.m., at which time his sufferings completely ceased.

The question can be asked, What caused the agony this man suffered? It could not be from the nervous structure of the parts concerned in the operation, as but few and small nerves are in this region. Could it have been caused by the urine, always a stimulating fluid, now perhaps increased by an alteration in its normal constituents? or is it a corroboration of what I have seen and has been observed by others, in some way connected with the agency of chloroform, which, though it removes all pain during the operation, yet does not guarantee the patient from an access of suffering, in some instances more intolerable during the dressing of the wound or stump than where such an agent had not been used during the operation. Future observations must decide upon this peculiarity connected with the administration of chloroform as a surgical anæsthetic remedy.

Six drachms of urine flowed per urethram fifty-two hours after the operation, and continued to increase daily until the wound was completely healed.

If, as in this case, the rapid and firm coagulation of blood can be in any degree attributed to the use of chloroform, it is an additional value derived from it, as it will be the means of preventing secondary hæmorrhage after operations.

For an exact and accurate analysis of the calculus, I am indebted to the kindness of my colleague Dr. Geoghegan. The weight of it was three drachms and ten grains. It had a double nucleus, consisting in each of phosphate of lime, with a little phosphate of magnesia and ammonia, with animal and colouring matters. The exterior shell, which forms the great bulk of the stone, is porous, moderately friable, and consists of lithate of ammonia in large quantity, with phosphate of ammonia and magnesia, and a little phosphate of lime. Intermediate between the two, and closely investing the double nucleus, is a compact layer, which, similarly constituted as the external, appears to contain, however, a larger proportion of triple phosphate.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ON THE STRUCTURE, FUNCTION, AND DISEASES OF THE LIVER; AND ON THE ACTION OF CHOLAGOGUE MEDICINES.

By C. H. JONES, M.D., F.R.S.

THE author first described the minute structure of the liver, which consisted essentially of a mass of nucleated cells or celloid particles, usually more perfectly formed than the cells either of the salivary or renal glands, presenting a distinct nucleus, with a nucleolar spot, an exterior envelope, and an included mass of soft, semi-solid, albuminous substance, which commonly contained a few oily molecules. In addition to these, in well-nourished livers, were numerous free nuclei, imbedded in albuminous blastema, which exhibited various stages of progress towards the mature or perfect cell. The oily contents of the cells were subject to great variation, both in the same individual and in different classes of animals; the less perfect the type of the respiratory process, the greater the quantity of oily matter in the hepatic cells. The cells in their general mass constituted the hepatic parenchyma; this might be subdivided into smaller portions, called lobules, which were separated from each other more or less completely by fissures, the fissures themselves being continuous with canals that ramified throughout the parenchyma, and which, from containing the portal vein and its associated vessels, had been termed portal canals. In reference to the mode of distribution of the vessels, originally so well expounded by M. Kiernan, the author remarked that he decidedly agreed with Theile, who denied the existence of the vaginal branches and plexus of the portal vein mentioned by M. Kiernan. The author quoted from a paper by Mr. Paget, who had described these vaginal plexuses to be derived, not from the portal veins, but from the hepatic arteries, from which they were completely filled, when both arteries and veins were at the same time injected. The interlobular portal veins were therefore derived directly from the portal veins; and those which appeared to be vaginal branches of the portal vein were its internal roots, by which it received the blood which had served for the nutrition of the hepatic ducts and other vessels of the liver. After alluding to the mode of ramification of the hepatic artery, and the divisions of the hepatic ducts following the branches of the portal canal, the author referred to the relation which existed between the ultimate ducts and the cells constituting the parenchyma of the lobules. The prevalent opinion had been, that these cells were exactly homologous to the cells of the renal tubuli or salivary vesicles, like them growing on a free surface open to the exterior. Hence some anatomists had believed they had detected a basement membrane, forming anastomosing tubes, constituting a true lobular biliary plexus. Others, unable to find a basement membrane, had described the ducts as continued into the parenchyma of the lobules, as channels without proper walls, mere intercellular passages. After referring to the researches and opinions of Weber, Müller, Professor Retzius, on the one side, and of Val Guillon, Gerlach, and Doctor Carpenter, on the other, the author stated that the views of Kölliker, who denied the existence of intercellular pas-

sages in the lobule, agreed very nearly with his (the author's), and conceded his main position, that the cavity of the ducts was quite shut off from the cells of the lobules or their interspaces. The structure of the ultimate ducts, which the author had first discovered, was peculiar, and seemed to indicate strongly that they exerted active functions, and that they were something more than mere afferent canals. The injection of the duct, in the livers of pigs, by the double method, using separately saturated watery solutions of bichromate of potass and acetate of lead, exhibited an abundant yellow precipitate in the fissures; but in very few parts did it penetrate the lobules, which must have happened if there existed a lobular biliary plexus, or a plexus of intercellular passages. The author conceived, therefore, that the hepatic ducts did something more than merely carry out already elaborated bile. The ultimate ducts were far too small, and too sparingly distributed, to be able to take up the bile from so vast a mass of cells as that which constituted the parenchyma. If the ducts did not extend beyond the margins of the lobules, of which the author had no doubt, then the bile must be transmitted from cell to cell; or there was a march of cells outwards from the centre to the circumference; or else the bile, arriving at the margin of the lobules, was taken up by the ultimate ducts in some unknown way. The author thought such assumptions groundless and unnecessary; and that the pathological state of fatty liver, as well as the fatty liver occurring naturally in fishes, showed that the secretion of the parenchyma was not identical with that of the ducts, for the gall-bladder could hardly contain deep-green bile, when the parenchyma was nought but a mass of oil. He concluded, then, that the parenchymal cells of the lobules did not merely secrete bile which was carried off unaltered by the ducts, but that the cells secreted biliary material, or some of its components, which were not fully elaborated or formed into perfect bile, except by the action of the ultimate ducts. Proof was then offered that the hepatic cells did not ordinarily contain bile, although it was commonly held they did. He believed that to be a diseased or exceptional condition, not found in the hepatic cells of slaughtered or healthy animals. Furthermore, a yellow tint in the cells was no proof of the presence of bile; it showed merely the presence of pigment, and yellow pigment is found in the fat of some animals, quite independent of biliary secretion. Chemistry must be resorted to, to solve the question of the presence of bile in the hepatic cells. The author had made alcoholic extracts of the livers of different animals, and having evaporated to dryness, the residue, when dissolved in water, failed to show, by Pettenkötter's test, any reaction characteristic of the presence of the bile. The author, however, did not wish to express a positive opinion, but he thought that the received opinion had need of more direct evidence, before it could be regarded as proved. He then detailed the mode in which the morphological structure of the ultimate biliary duct fulfilled the function of secretion. The chemical changes which the ultimate ducts effected, might be conceived according to the hypothesis of Lehmann; and a summary of our present knowledge might stand as follows: Sugar, oil, and a yellow pigment were found in the parenchyma of the liver; bile is not found there, but in the ducts; it is inferred, then, that the ducts, through their ultimate extreme portions, *make* the bile. The author next proceeded to detail some experiments made relative to the action of cholagogue medicines, the results of which led him to believe that mercury, muriate of manganese, and colchicum, were the only ones which seemed to increase the production of yellow pigmentary matter in the cells of the liver. They also increased the production of glycocholate and tauro-cholate of soda; but it had to be determined whether the quantity of these principles was always proportionate to the yellow pigment. It was clear that the cholagogue action of a medicine, its emulging effects on the ducts, was distinct from that which it excited in the production of biliary pigment. One very important effect of the administration of mercury on the liver was noticed to be congestion of this organ; an argument rather for-

bidding the use of the remedy in inflammation of the substance of the liver, a plan otherwise recommended by analogical experience. The author then passed to the subject of diseases of the liver; the microscopic appearances of fatty liver were detailed, and the question, what constituted true fatty degeneration of the liver, discussed. Was it a simple increase in the quantity of oil naturally existing in the hepatic cells, or was it a further and more important change? He believed the latter. In the liver of animals artificially fed on oily food, and subsequently examined, the cells, as well as the inter-cellular substance, were loaded with oil-molecules: the accumulation of oil was equal everywhere. But in the morbid state of fatty degeneration, the oil-drops were not enclosed in distinct cells, but appeared to lie in an indistinct and granular, or semi-fibrous substratum. Another point of difference consisted in the absence of sugar in true fatty degeneration; while in the liver of an animal fed on oily food to produce a fatty liver, sugar could be detected. Another point of importance was the limitation of fatty degeneration to the margin of the lobules; it was not a mere accumulation of oil in the marginal cells, but a destruction of those cells; a liver thus affected presented the lobules marked out by a zone of opaque matter. No satisfactory explanation of this tendency of oil to accumulate in the marginal cells could be offered. Fatty degeneration of the liver might occur in very different diseases; it was by no means peculiar to phthisis. Reference was then made to the waxy liver of Rokitansky, with which the author was not sure that he was acquainted. Cirrhosis was then mentioned, and Rokitansky's description quoted, as also that of Dr. Budd, whose views expressed the opinion ordinarily received, but from which the author in some degree dissented. The author believed that an unhealthy nutritive process was the essence of cirrhosis, and might be developed in one of three situations.

1. In the larger and moderate-sized portal canals, excluding only the smallest.
2. In these last and in the fissures.
3. In the smaller canals and fissures, and in the substance of the lobules.

The first form produced common *hobnail* liver; the second and third, the tough, firm, dense liver, sometimes termed brawny. The author considered cirrhosis to represent essentially a degenerative process, and to arise from the effusion of an unhealthy plasma, not only in the canals and fissures, where it induced unnatural increase, but also in the external part of the lobules, where it passed into a solid form, and constituted an amorpho-granular substance, compressing the capillaries and obstructing the secreting cells. The thickening and condensation of the fibrous tissue in the liver were thus not so much the effect of an inflammatory action, as of a low degenerative process, analogous to that which stiffened the valves of the heart and contracted the orifices; and which view the author thought was supported by the results exhibited in a table appended to the paper. The subject of jaundice next received attention. This was a disease that manifestly resulted from the conveyance into the blood of bile pigment, a constituent of the bile which was essentially excrementitious, and intended to be cast out with the faecal matter. In many cases it existed only as retained excretion; in others it seemed to be formed in excessive quantity, as in the acute yellow atrophy of the liver. Yellow matter was often found in the central cells of the lobules, and nevertheless there was no jaundice. It should be borne in mind, that the yellow pigment, as it existed in the cells, did not evidence the presence of biliary matter, of cholic acid, or its conjugates. The yellow matter could be extracted by alcohol, and its characteristic reaction obtained by nitric acid, but Pettenkötter's test decided against the presence of any organic biliary acid. The deep colour of the urine in jaundice depended on the presence of bile pigment solely; no trace of cholic acid was discoverable. The author considered the majority of cases of jaundice to depend on the absorption into the blood, not of completely formed bile, but of one of its constituents only, the yellow pigment; and this might take place in one of three ways: 1, by a mechanical obstruction to the flow of bile into the intestine, through the ductus communis choledochus; 2, from

inaction of the elaborating ducts; 3, with or without impairment of the action of the excretory ducts, when an increased quantity of yellow pigment was formed in the parenchyma of the liver.

### MEDICAL SOCIETY OF LONDON.

MR. GAY detailed the following particulars of a case of  
MALIGNANT ULCERATION OF THE MAMMA.

S. W., aged 37, a small, delicate-looking woman, admitted July 11, 1851, into the Royal Free Hospital. Had been married seven years; was the mother of several children, and enjoyed good health until about ten months since, when, during an attack of cold, attended with a most severe cough, her attention was drawn to some soreness which she felt in her left breast. She became pregnant at this time, and subsequently noticed that the affected breast was larger than the other. This caused her to apply to a medical gentleman, who pronounced that the breast was cancerous. (Mr. Paget saw it about this time, and was of the same opinion.) The increase of the breast in size, in consequence, it is presumed, principally of utero-gestation, was attended with severe pain; indeed her sufferings were so severe that she did not as usual heed the pains of labour. Ten days after her confinement, she was removed to a metropolitan hospital, where ice was, according to her account, kept continually applied for more than a week. (The integuments of the breast had become of a dull purplish colour prior to the application of the ice.) After a fortnight she was taken to the Royal Free Hospital. The left mamma was about double its ordinary size, of a uniform dull bluish or purple colour, smooth on the surface, having the nipple erect, immovably fixed to the parietes of the chest, and cold. An unhealthy-looking, small ulcer was situated just beneath the nipple, which had but just made its appearance. The skin immediately surrounding the breast was of the same colour, which gradually shaded away into the colour of the healthy skin. The pain was excessive. Her condition and that of the breast almost remained stationary until the 22nd, when the ulcer became a kind of deep fissure, extending across the breast as far as the edge of the arm-pit. From this time pieces of sloughy and decomposed tissue began to separate; these became larger as the destructive process extended deeper. On the 27th, large masses of the pectoral muscles came away; and on the 28th, it was evident that an aperture had formed into the pleura. Portions of two ribs were now brought into view, and these became necrosed, whilst the joints with the sternum were found, on post-mortem examination (six days after), to have become completely destroyed. The wound increased in size in most directions, whilst in the upper part there were indications of healthy granulations. Her breathing became more laborious; her strength failed; and she died on the 3rd of August. The wound, as observed after death, occupied the whole of the pectoral region, and ran back into the axilla; and the sloughing by which the breast, the integuments, the muscles, the bones, and the pleura pulmonalis, became successively invaded and destroyed, occupied altogether but twelve days. Mr. Gay said that he was indebted to Dr. Marsden, under whose care this patient was, for having had the opportunity of making the foregoing observations. Drawings illustrative of the progress of the disease were exhibited.

MR. GAY also related the following case of  
TUMOUR OF THE ARM.

Mrs. G., aged 58, presented herself to me about a month since, with a tumour of the forearm. It commenced about two years before, in the upper part, and gradually increased to the size it has now attained—fifteen inches and a half in circumference. The whole of the forearm is enormously enlarged, obviously by a growth occupying a situation beneath the superficial muscular masses and vessels. It is uniformly hard, slightly elastic, and attended with severe pain at times, although she does not suffer materially from its being pressed upon. Large, bloated veins are seen

creeping along the integuments, whilst the elbow-joint and fingers are immovably flexed. The axillary glands were healthy. The general appearance of the patient was unhealthy; her skin was jaundiced, tongue furred, pulse quick, and her bowels constipated. The case reminded me forcibly of one, in every respect, as far as the external indications were concerned, similar, which was under Mr. Thomas Wakley's care some time since, in the Royal Free Hospital. I felt little hesitation in looking upon this as a case of encephaloid disease, as it turned out to be in Mr. Wakley's case; and looking at the condition of the patient, I recommended, after improving her general health by a suitable course of medicine, that the limb should be amputated. She cheerfully submitted to the operation, which was done with little loss of blood. The muscles, as they were cut through, presented the unusually dark appearance which is, as far as my experience goes, common in persons with malignant disease, and a considerable number of vessels required ligature. The patient is doing remarkably well. On dissecting the arm, the superficial muscles were found to be spread out in one thin layer over the tumour. The tumour itself was found occupying the whole of the forearm, lying between these and the deep flexors, very loosely connected by fine cellular tissue to the structures which enveloped it. The median nerve was attached along its back part, and indeed situated in a superficial groove which it had formed for itself in the substance of the tumour. On cutting through, it appeared to the sight to be made up of two lobular masses, closely connected with each other; the one, in every respect, resembling colloid, the other, encephaloid, cancer. The microscope, however, could not discover any traces of the usually acknowledged cancer cell; and according to Mr. Paget, by this test it would seem to be a simple fibro-cellular tumour. According to my own observation, it was composed of areolar tissue, in large quantity, small fat-granules, and peculiar laminæ, in the forms of irregular-shaped discs, without nuclei or granules. These laminæ were found especially in those parts of the mass which had a cream-like, encephaloid appearance, and not in the transparent, gelatinous, greenish portions, which had a very distinct colloid look, and contained areolar tissue alone.

Mr. Gay informs us, that since the case was related to the Society, Dr. Richard Quain has examined a portion of the gelatinous matter of the tumour, and that the following is his report thereon:—"I find the gelatinous portion of the tumour composed of an extremely fine filamentous tissue, forming a loose web, which is probably infiltrated with some serosity, so as to cause this jelly-like appearance. There are diffused through it a few cells, about the size of the white blood-globules, filled with minute granules. There are also some oily particles. The opaque substance is composed almost entirely of cells, which are arranged in rows and laminæ, so as in some degree to constitute fibre-like bundles. These cells are separated with difficulty from the texture, but when seen they are multiform, small-sized, granular, and nucleated. There is much fatty matter in various points. There is nothing which would lead me to assert positively that this is a non-malignant tumour; indeed, general appearances incline the other way. The case is one which is worth watching."

### LARGE OVARIAN CYST; REMOVAL.

MR. I. B. BROWN exhibited a large multilocular cyst, which he had lately removed from a young married woman at St. Mary's Hospital, by extirpation. A firm band of adhesion existed, about a quarter of an inch in width, attached to the middle lobe of the cyst anteriorly, and extending in the right hypogastric region, where it was firmly adherent to the parietal walls. This band was divided to enable the mass to be removed, and no blood appeared to flow; but the patient gradually sank on the third day after the operation, and a post-mortem examination discovered that the band of adhesion contained two bloodvessels, and from these had flown fourteen pounds of blood, which was surrounding the bowels and occupying the pelvic cavity, most of it in a fluid state, some of it in coagula. The ligature

around the pedicle was so firm and tightly applied, that it was impossible that any blood could escape from the vessels there. This cause of death was of great practical interest, and Mr. Brown stated that he was not aware of a similar case, and it was therefore of importance to be known by every surgeon who performed ovariectomy.

Dr. S. W. J. MERRIMAN read a paper on

#### ARTIFICIAL DILATATION OF THE OS UTERI.

The author, conceiving that the true principles of midwifery have recently been assailed, gave, concisely, arguments from various sources, why it is improper to accede to the proposal to use the fingers as dilating agents in the first stages of tedious labours. No accoucheur can attain true celebrity, he said, who is unable to discriminate between the two principles of action—viz., when to leave the case entirely to Nature, when to render aid. He first referred to the opinions of ancient and almost modern writers, who all advocate this plan of treatment by manual dilatation, and stated that their habit of speaking of the os externum vaginæ as the os uteri, and their belief that the child by its own efforts conducted to the opening of a passage for itself, rendered their advice useful only as a matter of history, not as a rule of practice for the present day. He expressed his surprise at finding such recommendations brought forward at the present time, the reasoning on which the advice was founded being so completely at variance with what we know to be the real state of the case. He then proceeded to the writings of accoucheurs published 100 years ago, and stated that the same advice was found in them, coupled with much else that is now obsolete, because injurious. The learned Smellie, who did so much for the practice of midwifery, was instanced as having gravely recommended and practised dilatation of the os externum by the hand formed into a conical shape, in order that he might pass his hand flat between the head of the fetus and the os uteri, believing that to be the best way of preventing “the os uteri being pushed before the head of the child.” That such advice should be followed, or even referred to as evidence of the applicability of the practice, was inconceivable, especially when coupled, as it is, with recommendations to press back the os coccygis to make room; the principle of Smellie’s usual conduct being to do as much as possible himself, and to leave very little to Nature. Passing on to modern authors, he showed that Burns expresses his belief that the first stage of labour, or the complete obliteration of the os uteri, should be accomplished in a certain time; and that Dr. J. Hamilton limited the time to twelve or fourteen hours of constantly recurring pains, and recommended artificial dilatation by the fingers if the complete opening of the os were likely to be delayed beyond that time. This brought us to a reason alleged which could be fairly considered—viz., that danger necessarily accrues if the labour last many hours—over twenty-four hours, for example—the term usually assigned to a natural labour. This doctrine he controverted in the following manner. Allowing that Prof. Simpson’s analysis of Dr. Collins’s tables shows that danger to life does increase as the duration of labour is prolonged, he did not consider that danger of much moment, compared with the very great majority of perfectly natural labours of short duration; the question being rather, whether dilatation by the finger does not produce as much injury as the prolongation of the labour would. He brought forward the following statistics, from Dr. Collins, that out of 15,850 labours of all kinds, the period of which was noted, 13,412 were over within six hours; 1672 additional within twelve hours; and only 766 were prolonged to twenty-four hours; the total mortality being 158. Dr. Joseph Clarke, of Dublin, attended at 3878 births, in his private practice, and lost none from the effects of protracted labour. In his hospital practice he enumerates 9748 ordinary labours over within twenty-four hours, with 71 deaths, and only 183 similar cases prolonged beyond that time, 37 of whom died; but 49 had required craniotomy to be performed, the head being impacted. The author says—“We have therefore very strong reasons for

being in no hurry to hasten the progress of labours, seeing how very large a majority terminate speedily, and how trifling the mortality is from the mere length of time occupied.” Pressure by the fingers could not, it was shown, act on the os uteri like the bag of waters, or the head when moulded into a lengthened shape. There could be no reciprocal action between the force pressing upon the cervix and the power of the uterine structure to endure the pressure. The accoucheur cannot tell by the mere motion of his finger what amount of space there is for the head to occupy; and he will seldom succeed in keeping up the lip of the os, except in the last moments of a protracted first stage of labour. Fissures of the os uteri in labour, with enlargement and ulceration, so called, of the cervix, about which so much has lately been said, were briefly alluded to; the cause of these post-parturient complaints being considered a want of tone in the uterine vessels, contraction not duly taking place after labour, or, in other terms, there being a want of re-absorption of the enlarged uterine structure. The author considered that pressure on the os uteri in artificial dilatation must bruise the part, and render it unable to resume perfectly its pristine condition. The os is treated as if not possessed of sensibility; the sensibility to external objects may be slight, but the distribution of nerves of the organic class is abundant, and they cannot fail to receive injury, and so impede the return of the part to a healthy condition. The necessity of bleeding and tartar emetic to overcome congestion, where pressure has been exerted on the os uteri, pushed down before the head, was also briefly alluded to, as an argument against using artificial pressure in ordinary cases. The author proceeded as follows:—“The temptation to endeavour to hasten a slow labour where the patient resides at a distance, where the fee is small, and a sufficient income can only be got by incessant occupation among a number of patients, is too strong to be resisted; the smallest concession to the desire to afford manual assistance in some peculiar cases is certain to be extended to others, where the necessities of the practitioner are so many. We ought therefore to set our faces boldly against any proposals, the following of which is likely, almost certain I might say, to be injurious to the mother.” Then suggesting that the “passing the finger gradually round the os uteri” may produce its effect in a secondary way, by enabling the accoucheur to regulate the mother’s expenditure of force upon her uterine organs, by observing whether her powers are equal to the task, and giving nourishment or medicine as required, he concluded thus:—“I look upon labour as essentially a natural, healthy process, yet verging upon disease. The accoucheur’s business is to preserve health, not to promote disease; he may hasten a labour by interference, but the interference of dilatation of the os uteri by the finger ought not to be made, except there is that amount of pressure upon the anterior lip of the uterus which would soon bring on congestion if it were not moved out of the way.”

#### TOPICAL MEDICATION OF THE LARYNX.

Dr. COTTON brought under the notice of the Medical Society of London a new method of applying a solution of nitrate of silver, or any other substance, to the laryngeal mucous membrane. After making a few remarks upon the practice of introducing a piece of sponge *within* the larynx, which he believed to be not only practicable, but, in the majority of cases, useful, and always with proper precaution harmless, he had nevertheless become convinced, from a number of experiments at the Consumption Hospital, that it was better merely to drop the solution into the laryngeal opening. This was easily accomplished by means of the simple instrument he presented to the Society, which was made by Mr. Coxeter, and consisted of a pair of forceps slightly curved, and having a small piece of sponge attached to one of its blades. By depressing and slightly drawing forwards the tongue by the ordinary spatula, the extremities of the blades might be held over the larynx, and at the proper moment the contents of the sponge could be squeezed into it. Dr.

Cotton had used it successfully in a considerable number of cases, and had found that it was generally less disagreeable to the patient, and produced less spasm and cough, than the ordinary method of passing down the sponge itself; whilst it possessed the obvious advantage of making it impossible that the sponge could ever fall into the larynx, the closing of the forceps effectually holding it. The sponge would contain about half a drachm of fluid, nearly the whole of which might, if desired, be applied to the laryngeal membrane and its neighbourhood, the cough which invariably followed its use always ensuring its diffusion.—*Lancet*.

## EXTRACTS FROM CLINICAL LECTURES.

By JAMES SYME, Esq., Professor of Clinical Surgery.

### EXCISION OF THE SUPERIOR MAXILLARY BONE.

I PLACE this patient before you, in the first place, to show how little deformity may result from removal of the whole upper jaw-bone. When the extent to which it enters in forming the mouth, the nose, and the orbit, is taken into account, a very serious effect of this kind might be expected. But you see that, although little more than two weeks have elapsed since the operation was performed, the countenance is hardly at all disfigured, and the articulation is distinctly intelligible. In the second place, I wish you to remark that the process of removal was accomplished by means of one simple incision through the cheek, from the malar projection to the angle of the mouth. Since I performed this operation in 1829, for the first time in Great Britain, and placed the first case of its execution on the records of surgery, various modes of incision, more or less complicated, and even zig-zagging in four or five different directions, have been proposed. But as access to the parts concerned could not be required in any case more freely than in the one you have witnessed, and as the simple incision has proved amply sufficient for the purpose, I trust you will not hesitate to discard any prejudice that may have been acquired in favour of such needless and hurtful complications; for the more simply the integuments are divided, the more perfectly may they be reunited. And in the third place, I now beg to call your attention to the perfect adhesion which has been established in the case before you. The wound has healed literally without a drop of matter, and was apparently as sound three days after its infliction as at present. From its situation, if any perceptible trace were left, it would be covered in a male by the whisker, and in a female by the string of her cap. But even at this early stage it would require close inspection to detect the line of incision. Now this perfection of reunion has an important bearing on the principles of practice concerned in the treatment of wounds desired to heal by the first intention. For if the condition which afforded such a favourable result could be ensured upon other occasions, there would be no risk of the disappointments that so frequently occur; and although this unfortunately cannot be accomplished to the full extent, the knowledge of what is really required may lead a far way to success. It has long been a well-known fact in surgery, that penetrating wounds of the cheek adhere more readily than most other solutions of continuity to which the body is exposed; and various attempts have been made to account for this, on the ground of alleged peculiarities in the texture concerned, notwithstanding the obvious objection to such a view of the matter, that wounds of the cheek which *do not penetrate its whole thickness*, are no less difficult to heal by the first intention than those that occur elsewhere. The true explanation is, that a wound which penetrates into the mouth has two orifices—one external and the other internal; so that, while one is accurately closed, the other may remain open, for the discharge of blood that would otherwise accumulate in the cavity between the surfaces of the wound, so as to separate them and prevent their union. The grand essential for primary adhesion is, that the respective surfaces should be in accurate contact; and while they are not only so situated, in the first instance, but also protected from subsequent separation through the retention of blood or

other influences, their union is impossible, however conducive to this result the circumstances may be in other respects. In every wound, then, that you wish to unite by the first intention, you should employ every precaution to prevent the raw surfaces from being displaced, in regard to their respective positions; in the first place, by fitting them accurately to each other; hence the advantage of simple incisions; and, secondly, by so dressing them as to prevent the accumulation of blood. Having long laboured to establish this principle of treatment, I regret to see that a backward tendency has been in recent times manifested by the preposterous proposal of sealing up the wounds by collodion or other impermeable coverings.

### PAROTID TUMOURS.

James Jackson, aged 45, from Glamis. In the situation of this man's left parotid you see a tumour, which he says has existed since his earliest recollection, and which, in by-gone days, when pathological distinctions were less accurately drawn than at present, would doubtless have been regarded as an enlargement of the gland itself. It is equal in size to the half of a small orange, convex in form, with slight nodulation of the surface, and very firm in its consistence. Its root seems to be deeply seated, but not inseparably attached to the neighbouring parts. The growth has been so slow in its progress, as to appear stationary, until within the last few months, during which it has rapidly increased. This tumour is obviously of the fibrous or fibro-cartilaginous kind, such as is frequently met with in the mammary as well as the parotid region. It has originally no malignant disposition, but sooner or later tends to degenerate; and if it either inflames or softens, does not admit of removal with any permanent benefit. When formerly supposed to be morbid alterations of the parotid gland, such tumours afforded a fruitful source of discussion, in regard to the practicability of their extirpation. The late Dr. Barclay, in his anatomical course, used to devote a lecture to the consideration of this question, maintaining that the operation could not be accomplished without division of the portio dura of the seventh nerve, and the termination of the external carotid artery; while the irregular form of the gland, niched as it were into so many chinks and hollows, rendered the removal of its whole substance impossible. When such doctrines were in force, "Extirpation of the Parotid" was held to be a great feat in surgery; but since the true nature of the tumour so regarded has been established, it is seldom that any claim is advanced to the accomplishment of this achievement, except on the western shores of the Atlantic, where it is still occasionally the subject of a flourish of trumpets. In removing tumours from the parotid region, it is essentially necessary to obtain free access by an ample division of the integuments. The coverings should then be completely divided, so as to expose the surface of the growth. After this has been done, in regard to the whole superficial or external part of the tumour, the dissection should be carried on by turning its base from before backwards; that is, from the ramus of the jaw towards the mastoid process; and by cutting *upon* the tumour, so as to divide its connexions, without endangering the bloodvessels and nerves not implicated in its substance.

The tumour was removed in the way described: by means of a free crucial incision of the integuments, the convex external surface having been exposed and detached from the ear, a sort of neck was found thickly embraced by the displaced and compressed parotid gland, beyond which the growth extended to nearly the same bulk that it had done externally. The portio dura and large arterial branches escaped without injury. After the vessels that required ligatures were tied, no attempt was made to close the orifice of the wound, which would have prevented the further oozing of blood from having any outlet for its escape, and a large sponge was simply applied, with the support of a single turn of a roller. Adhesion took place without any trouble or difficulty; and as the tumour, when divided, displayed a surface of the firm fibro-cartilaginous kind, the patient left the hospital, with every prospect of future comfort, on the 19th of May.

## MAXILLARY ABSCESS.

A. B., aged 16. You see here a swelling of the face, which extends from the mouth up along the left side of the nose to the eye. It is of firm consistence, and the integuments are tense and red, so that at first sight the suspicion of a malignant growth is suggested. The patient tells us, that three years ago, while bathing in the sea, he fell upon a rock, and knocked out two of his front teeth in the upper jaw, the root of one being left in its place. He subsequently suffered much from toothache, but did not notice any swelling, until about a month ago, soon after exposure to cold and wet. Since then the stump had been extracted, and you now see that matter is discharged from the opening it has left in the gum. When a probe is introduced here it passes into the maxillary antrum, and the case clearly appears to depend upon an abscess of this cavity, originating from irritation of the broken tooth, and aggravated by constitutional disturbance from exposure to cold. In regard to the treatment, it might be thought that, as the matter can now escape through the alveolar opening, there is no occasion for further interference. But experience teaches us that suppurating cavities of bone, no less than those of the soft parts, require that the matter secreted from their surface should have *free* egress; and I have seen this disease of the upper jaw remain obstinate, although apertures for the discharge had taken place spontaneously through absorption in three different parts of the parietes. In order to establish the requisite drain, I now raise the lip, and thrust a bistoury between it and the gum, through the thin expanded bone, cutting horizontally, so as to make a large and dependent aperture. A piece of lint is introduced at first, to check any tendency to bleed, but so soon as this ceases, the opening will be left quite free. In the treatment of all sinuses, you should consider as *essential* a free and dependent aperture—as useless the employment of injections—and as injurious the introduction of plugs or tents. Not long ago I saw a Scottish nobleman, who, while resident in Paris, had been exposed to cold, and suffered from suppuration of the frontal sinus, of which the matter had made its way through the upper eyelid, and left a small aperture. The patient told me that he applied to a practitioner of the French capital, who had seen him once a day between three and four hundred times, without holding forth any prospect of his services ceasing to be requisite, under the pretext of washing out the cavity, and plugging its orifice, to prevent the admission of air. Certainly, without being uncharitable, we may conclude that this practitioner was rather peculiar in his principles as to either pathology or morality.

## POPLITEAL ANEURISM.

13th May. Peter Lamont, aged 29. In this case the operation was performed yesterday, with strict attention to the circumstances which I have explained as essential for safety. The artery was not exposed by scratching down to it with blunt silver or copper knives, it was not denuded more than sufficiently for allowing the ligature to pass, and it was tied, not loosely with a tape, or thick cord, or bundle of small ones, but by means of a single small firm silk thread, tightly drawn. The patient being sound asleep, under the influence of chloroform, of course suffered nothing at the time; and when he awoke, felt completely free from the pain which he had previously suffered from the disease. He is to-day in every respect perfectly well, and absolutely devoid of uneasiness in any quarter. This I mention not because it is unusual, but because it is what I led you to expect, and believe you may rely upon as the result of this operation when carefully performed on proper principles. Much blame has been attributed to me for adhering to it in opposition to the revival of pressure for accomplishing the same object, and which would certainly be deserving of adoption if there were no other more easy and safe mode of affording relief. But while quite ready to admit that the femoral artery may be tied in such an improper way as to place the patient's life in the greatest possible danger; believing, from upwards of twenty cases which have occurred in my own practice, that the artery

may be tied without any risk of bad consequences from the operation; and knowing that, when relieved by this mode of procedure, the patient escapes without any suffering whatever, instead of being exposed for many days and nights, or rather long weeks, to agony from the pressure of screws, with no small chance of failure on the one hand, and mortification on the other,—I must still consider it my duty to practise and inculcate the ligature as preferable to the “clamps.” But this I shall do without attempting to retaliate in the way of invective and personal abuse, which seldom strengthen any cause, and indeed generally proceed from the feeling of its weakness.

## EXCISION OF THE HEAD OF THE HUMERUS.

Janet Stoops, aged 60. We yesterday ascertained the truth in regard to this case, and did what I trust will prove sufficient for the patient's complete relief. You recollect that at our last meeting I expressed my doubts as to the precise seat and nature of the disease. It was plain, from the sinuses leading to the joint, the copious discharge, and the long duration of the symptoms—viz., for five years—that there was some morbid derangement in the extremity of one or both of the bones composing the articulation. But whether this was an exfoliation, such as you witnessed in another case the same day, or caries; and whether this condition, if really existing, was limited to one, or extended to both bones, were questions which neither the history of the case nor the most careful exploration of the sinuses seemed sufficient to determine. With exception of the lower jaw, the humerus is more prone to exfoliation of its articulating extremity than any other bone in the body, the softer cancellated portion being usually absorbed, and merely the dense part left, so that a very scanty representative of the original bulk remains. Some of you may recollect a case of this kind that occurred last winter, in which the exfoliation removed very much resembled in size and form an old-fashioned watch-glass. Another result of inflammation affecting this bone, occasionally met with, is partial absorption of the head of the bone, with caries of the remainder, which is then hollowed out into a cavity, the external surface being sound and the internal diseased. Such was the state of matters in a woman on whom I operated twenty-six years ago. She had suffered for six years, and been dismissed as incurable from this hospital; subsequently came under the care of Mr. Liston, who proposed nothing for her relief, and finally submitted to an experiment which I proposed. This was to cut into the joint, and ascertain the true state of matters, which proving to be an excavated state of the head of the humerus, was easily removed by excision of this part, so that the patient gradually regained her strength, and lived in good health, with the nearly perfect use of her arm, for ten years afterwards. But there is still another form of disease, and unhappily more frequent than either of the others, in which the field for surgical interference is less satisfactory. This is caries of both the articulating surfaces, in which case I regret to say there is no mode of affording effectual relief, except amputation of the arm at the shoulder-joint, followed by free removal of the diseased portion of the scapula. In such circumstances I have repeatedly performed excision of the articulation, but always with an ultimately unsatisfactory result; while in cases of the most unfavourable character, the more severe measure has no less uniformly proved successful. In the case which you witnessed yesterday, being uncertain as to the precise seat and nature of the disease, I made an incision directly downwards from the acromion, sufficient to admit my finger into the joint, and allow the extraction of any exfoliated portion of bone that might be detected; while it admitted of extension in the event of a more serious operation being found requisite. Having found and removed two exfoliations from the head of the humerus, I ascertained that the remaining portion of it was excavated into a cavity, while the glenoid surface of the scapula was quite sound, and therefore extended the incision downwards and backwards to one of the sinuses, which opened at the posterior margin of the axilla, guided

a knife round the head of the bone, thrust it through the wound, by carrying the arm forwards across the duct, and sawed it off. The patient has been quite easy since, and will, I trust, make a good recovery. She went to sleep under the chloroform, fully prepared to part with her arm, and was not a little pleased to find, upon awaking, that she still retained it.

#### UNUNITED FRACTURE.

There are at present under our observation four cases of ununited fracture. Two of these were sent from different parts of the country, as hopeless subjects of ordinary treatment, the long period of nearly six months having elapsed since the occurrence of their respective injuries. They were both admitted on the same day, about two months ago, and I then explained that the great source of such conditions being the want of sufficiently complete rest during the period of consolidation, I entertained a sanguine expectation of effecting reparation through the maintenance of absolute immobility of the broken bones. I stated that ununited fracture of the humerus might be regarded as nearly, if not altogether, irremediable by any means hitherto contrived, and that this was fortunately of little consequence, as the muscles of the limb were so equally balanced as to render it useful for most purposes, notwithstanding the defect of rigidity. But in regard to the other bones liable to this derangement, and more especially those of the thigh and leg, which are most frequently the subject of it, I was able to say that, in the course of twenty-five years' hospital and private practice, I had always succeeded in restoring firmness, by mere attention to the ensurance of stability in the position of the limb; and I expressed a strong impression, almost amounting to conviction, that various means of remedy, such as setons, subcutaneous division, ivory pegs, &c., owed any share of credit which they had acquired to the care, conjoined with their employment, to keep the bones quiet. The plan I have pursued is founded upon there always being in such cases more or less deformity, from the yielding state of the bone no longer resisting any excess of muscular contraction that may exist on one side of the limb. There is thus established a preternatural convexity, upon which I place a cushion or folded sheet, and upon this—after being secured in its place—a splint of wood, long enough to extend, in the case of the leg, from the knee to the ankle; and in that of the thigh, from the ribs to beyond the foot. Bandages are then applied above and below the cushion, so as to draw the distorted limb towards the splint, and render it not only straighter, but at the same time completely immoveable. In many cases of six, eight, or even twelve months' standing, the application of this simple principle has proved completely successful, and, as already stated, I have never found it necessary to employ any other measure. The two patients now under treatment—in one of whom the thigh, and in the other the leg, is concerned—have been much slower than usual in their progress towards recovery, but are now very nearly quite strong, and the limbs, which were much deformed, are perfectly straight. In the third case at present under our observation, the fracture is seated a little below the neck of the humerus, in a patient who suffers from palsy of the deltoid and other muscles, which has doubtless prevented reunion by not exercising the usual bracing effect upon the broken surfaces, and renders the prospect of recovery even more than usually hopeless. The fourth case has been treated from its commencement in the hospital, the patient being a young man, J. C., aged 18, who was admitted on the 10th of January for compound fracture of the leg. A large portion of the tibia was detached at the time of the injury, and an additional portion subsequently exfoliated. The greatest care was taken to keep the limb quiet in a good position, and every thing went on favourably, except that no firmness was regained. The wound has been healed for many weeks, but still the bone remains flexible, as if there were a fibrous substance interposed between its extremities. My explanation of this result is, that the fibula not having sustained a loss of

substance commensurate with that of the tibia—or rather any loss of substance at all—has maintained the leg of its original length, and prevented the surfaces of the tibia from approximating to each other within range of the ossification; just as in the experiments of Sir A. Cooper on dogs and rabbits, where a portion of only one bone of the fore-leg was removed; it being always found that when the portion removed exceeded a small limit, the osseous extremities were united by a fibrous medium. According to this view of the case, the most likely mode of affording relief would seem to be cutting out the fibrous substance which has been formed between the ends of the tibia, and at the same time, in order to promote their requisite approximation, removing a portion of the fibula. Such an experiment appears justifiable under the circumstances, and shall forthwith be put to trial.

#### CLUBFOOT—VARUS.

This child, seven months old, has been brought from the country, or rather a distant town, on account of congenital deformity of the right foot. You see that the toes are turned inward, while the heel is drawn up, so that the little patient, if able to stand or walk, would rest upon the outer edge of the metatarsus. I now divide the tendo-Achillis by subcutaneous incision, and the heel is at once set free; but the inversion is still obstinate, and I therefore in the same way divide the tendon of the tibialis anticus. Immediately upon which the foot admits of being straightened, and kept in this position by means of a simple splint. This will be allowed to remain for two days, when what remains requisite for complete recovery may be trusted to a leather boot, with firm sole and sides, laced in front. Such is the simple process by which the worst forms of clubfoot are now easily remedied; and there is no triumph of modern surgery more creditable to the advance of our art than the control thus acquired over one of the most unseemly, inconvenient, and previously unmanageable deformities to which the human body is subject. The author of a surgical work lately published in London (Mr. Bishop), and which, from the opinions of the medical press, seems to be much admired in that part of the world, has endeavoured to show that the force transmitted through the tendo-Achillis tends to cause eversion of the foot, or that form of clubfoot named *valgus*, and after a demonstration to this effect, proceeds to say:—"Hence it is obvious, that if in talipes varus the tendo-Achillis is cut, it must increase the mischief." Now, the case which you have just witnessed will enable you to appreciate the incredible absurdity of this statement, so opposed to common sense and inconsistent with daily experience. Fortunately for you, Edinburgh does not possess any orthopædic institutions, or fistula infirmaries, or cancer hospitals, so that the whole field of surgical practice is placed under your observation, instead of being divided into sections, and committed to the charge of specialists, whose claims to confidence in their peculiar department seldom amount to more than their admitted obscurity in regard to the whole subject. You are thus able to judge from what you see, and will I trust never permit the misrepresentations of sophistry to mislead you from the true path of experience.

#### WOUND OF THE RADIAL ARTERY.

May 17th. J. S., aged 40, from Kinross-shire, states that while pruning a gooseberry bush he accidentally thrust the knife into his left forearm, at the lower part of its upper third. Blood gushed out, he said, as when a pig is stuck; but was partially checked by the pressure of his thumb on the wound, and afterwards more effectually restrained by a medical man, who stitched together the edges of the orifice, and applied a bandage. Still the bleeding repeatedly recurred, so as to require the further protection of a tight band applied above the elbow; and on the following day induced him, with the advice of his attendant, to come here for some more effectual relief. Having removed the bandage, I found a pulsating tumour at the seat of injury, which was laid freely open by dividing the stitches and extending the incision through the integu-

ments. The clotted and fluid blood being sponged out, while pressure was made above the elbow, I dilated the opening through the fascia and muscles, so as to expose the injured vessel, which proved to be the radial artery, passed a double ligature under it, and tied one of the threads on either side of the aperture in its coats. The patient has suffered no inconvenience, and is not likely to do so. You thus see the advantage of adhering to the important principle of practice so powerfully advocated by Mr. John Bell, which was to tie arteries that required to be tied for hæmorrhage by exposing them at the seat of injury. The general rule is, that arterial hæmorrhage should always, if possible, be arrested by local means directly acting on the wound. If the artery concerned be at or below the wrist, or at or below the ankle, pressure, if properly employed, will always prove sufficient; but if the vessel injured be of a larger size, a ligature on each side of its aperture is the proper measure for security. If in this case which you have seen, I had tied the brachial trunk, hæmorrhage would have still been maintained through the free anastomosis of its branches in the forearm; and if pressure had then been applied, the impoverished limb would have readily passed into a state of mortification. Many arms, and not a few lives, have fallen victims to this error of practice.

#### AMPUTATION OF THE ANKLE-JOINT.

There are at present in the hospital two cases requiring amputation at the ankle-joint. In the girl, aged 14, who is now before you there is extensive disease of the tarsus, not leaving room for the performance of Chopart's operation, even if I deemed it expedient, which I have long ceased to do, from conviction of its inferiority to that at the ankle, especially in regard to the protection afforded against relapse. In one year alone, I performed three secondary amputations at the ankle to remedy the sequelæ of Chopart's operation. This patient has been sent here to suffer whatever may be thought necessary, and I do not hesitate in deciding upon amputation at the ankle, which, while effectually removing the disease, will enable her to retain a limb hardly diminished in length or impaired in utility; and, what is of still more consequence, will expose her life to much less danger than removal of the leg would do. This difference depends upon the smaller portion of the body abstracted, upon the branches instead of the trunks of bloodvessels being divided, and upon the cancellated texture of the articulating extremity which is exposed, instead of the dense substance and medullary cavity of the bone. That the operation would prove safer than amputation below the knee, I anticipated from theoretical considerations, and am now able to establish on a large experience. If a patient's dissolution is inevitable from other causes, I do not mean to say that cutting off his foot will save his life; but the operation itself I believe to be as free from risk as the removal of a finger or a toe. The great and obvious advantages just mentioned have quickly established amputation at the ankle-joint in Scotland and most parts of the Continent; but in England and its capital the progress of the operation has been very slow; and as so many of you are connected with that country, I may mention what seems to me the probable explanation of this. If Mr. Liston had lived longer, the case, I believe, would have been different, since he had adopted this mode of amputation, and shortly before his death performed it twice with complete success: the second of these operations being the last he undertook. I had an opportunity of seeing both the stumps, and can testify to their excellence. But of the surgeons at present in London, the only one who has openly espoused amputation at the ankle-joint is the Professor of Surgery at King's College, who some time ago published five or six cases of its performance by him; in all of which, with one exception, so far as I recollect, there happened either death of the patient or mortification of the flap. Indeed, he at the same time expressed his conviction that sloughing was unavoidable. Now, such untoward advocacy, such damnable evidence, professing to come from a friendly quarter, could not but prove more detrimental to the character of an

operation than either silence or direct hostility; and when from the same, as well as other sources, were added representations as to the extreme difficulty of the operation, together with serious doubts as to the comfort and usefulness of the resulting stump, it is not surprising that there has been excited a prejudice which may require some time for its removal. Upon you who have an opportunity of judging from your own observation, rests the obligation of counteracting such groundless and injurious misrepresentations. You see that the operation is accomplished, without the slightest attempt at hurry, in less than a minute, and therefore cannot be very difficult, that the flap does not slough, unless through some error in the operation or after-treatment, and that the stump is so perfect that it may be used, even without any protection whatever, for standing, walking, or running.

#### UNUNITED FRACTURE OF THE FOREARM.

By a curious coincidence, you have here another opportunity of seeing the effects of ununited fracture; and having already witnessed it in the arm, leg, and thigh, now see it in the forearm. The patient, a man aged 24, tells us that his arm was broken six weeks ago, and has been treated carelessly. There is now a distinct convexity backwards, with swelling of the limb, and nearly complete loss of power in it. Both bones appear to have been fractured about the middle of their length, and there is here a slight degree of mobility. In these circumstances, I expect you will have a favourable instance of the treatment lately recommended; which consists in fixing a cushion over the convexity, applying over this a splint, and then drawing the ends of the bones towards it, so as gradually to render the limb straight, and constantly maintain the broken part perfectly free from motion.—*Edin. Jr.*

#### ENTROPIUM PROVED TO DEPEND ON MUSCULAR ACTION.

By HAYNES WALTON, Esq., F.R.C.S.,  
Surgeon to the Central London Ophthalmic Hospital, and  
to St. Mary's Hospital, Paddington.

I HAVE founded the treatment on what appears to me to be the pathological interpretation of the affection, and of which the indications are, to overcome the means of inversion by dissecting away the thick marginal portion of the orbicularis, supposing that part of the muscle to be entirely, or nearly all that is at fault, and also to remove as much of the skin of the lid as may be required by its loss to produce such tension as shall overcome and restore to a natural state, whatever unnatural position the other tissues or component parts of the lid may have acquired, from the irregular position into which they have been thrown by the muscle, and which has been made more or less permanent by such changes as inflammation would produce.

Now, as to the manner of operating: let us suppose that the right eye is to be done. An assistant stands behind the patient, and having made the lid tense by drawing it outwards and raising the brow, two incisions are to be made through the skin and muscle, one along the edge of the tarsus close to the cilia, and the second about the quarter of an inch above, and meeting the other at the extremities. The flap thus isolated should be dissected vertically from the one side to the other, and not taken away by horizontal strokes of the knife, or else the muscular portion will not be effectually removed. The wound should be very carefully sponged during the operation. Any arterial jet must be checked by temporary pressure with the finger. I have never found a ligature to be necessary. The exposed surface must be inspected, and, if any muscular fibres have escaped, the forceps and knife must be re-applied. The assistant should not desist until the knife has been laid aside, for the proper retraction of the skin is essential to steady and effectual dissection. Three or four sutures should be used. The cilia might appear to be in danger of being dissected off, but in reality they are not. A part only of the dissection is over them, and by the loose cellular connexion, the muscle is readily raised from the dense fibro-cellular tissue in which they lie.

The previous observations almost demand a cursory view of the usual methods of operating, and their results; indeed, I think this paper very imperfect without it; yet I fear that its introduction would make my communication too long. I must be satisfied with making the assertion, that there is not any known method of operating for entropion, that can be depended on, except that of cutting off the greater portion of the lid, and which is as bad in principle,—nay, even worse, if the physiological relations of the lid be taken into account,—as to amputate a thigh to cure a popliteal aneurism.

Heretofore, when an operation for entropion has been undertaken with the design of removing any part of the orbicularis palpebrarum muscle, it has been executed on very different principles, and in a very different manner to that I now advocate, and with very different results. The marginal part of the muscle, the musculus ciliaris, has been untouched, and only a bit of the centre of that on the lid has been snipped out. The only exception I know of is in the practice of Mr. Key. I am astonished that the notice of the operation he performed, and which is in the *Lancet* for 1825, page 235, should have escaped the attention of our writers on ophthalmic surgery. It is very lately that I have been acquainted with it, long after I had matured my own views. I cannot say whether Mr. Key continued to execute it, and what were his ideas on the subject in later years. The report runs thus:—"Mr. Key considered the inverted state of the tarsus to arise from the action of the orbicularis palpebrarum muscle. With that view he determined on laying bare the substance of the lower tarsus, and dissecting off the fibres of the orbicularis. The operation was performed by first turning out the lid, and then making an incision through the skin along the whole length of the lower eyelid, at a few lines distance and below the ciliary ridge; the integuments were carefully elevated by means of dissecting forceps, and the fibres of the orbicularis thus exposed were as carefully removed; there was considerable bleeding from the parts; the portion of skin which had been raised was laid down, and the wound dressed by means of adhesive straps, with a compress applied on the skin. The result is said to be successful. Mr. Tyrrell and Mr. Travers had operated previously, the first by cauterisation, the second by removing a portion of skin without success."

M. Desmarres has not overlooked the influence of the orbicularis in producing the inversion, and he gives a case that he thinks solely due to it; but he does not recognize its general operation, and he significantly indicates how little he appreciates the principle of Mr. Key's execution, and the triumphant issue of the case, by asking, in a commentary on the proceeding, "Is it to the incision of the skin, or the excision of the muscle, that the success is owing?" Spasmodic action of the muscle is spoken of by foreign authors, but with much difference of opinion concerning its frequency in producing entropion. The usual Continental mode of operating on the orbicularis is subcutaneous incision, which seems to have been unsuccessful; that of M. Janson de Lyon is a terrible affair, the cutting out of several vertical portions of skin, including some fibres of the orbicularis. Dr. Mackenzie, in his only notice of operating on the muscle, informs us, that it may be proper, after removing the cutaneous fold, to snip off a few fibres, so as to form a firmer cicatrix, actually fixed to the cartilage; and Mr. Lawrence, a much later author, echoes the same thing, for he writes, "In an incipient case, it may be sufficient to excise a portion of skin; this remedy will, at least, answer the purpose for a time. To make the operation more effectual, a portion of the orbicularis should be removed also, that a firmer cicatrix may be produced; or the acid may be employed, using it more freely, so that its action may extend deeper, and a solid scar be the result."

A narration of cases, with the various symptoms and terminations of entropion, must be excluded from this paper, which is intended to embrace only general principles.

As trichiasis commonly exists with entropion, and the

operation I have advocated bears on the united affections, I shall say a few words relative to it.

With inversion of the upper lid, there is not unfrequently decided trichiasis, and, whether the two are due to the same exciting cause, or the trichiasis have been the original affection, or merely an effect of the inversion, it matters nothing as far as the treatment is concerned; yet it may not be amiss to remark, that, with severe entropion, the edge of the lid can rarely for any length of time escape from being affected by the general inflammation, and that the cilia will the more readily retain any unnatural position in which they may be placed. And I am inclined to regard the trichiasis more frequently as an effect, because it is generally of one form, that of a separation or twisting in of the innermost of the cilia from their fellows, and that without any alteration or degeneration in the individual hairs, and because the removal of the entropion is generally sufficient to clear the globe of them. Although, practically speaking, such a degree of trichiasis matters little, it is important, before operating for the entropion, to ascertain whether there is also trichiasis, and whether the restoration of the lid to its natural position will or will not counteract the mal-direction of the cilia. Should it not be sufficient, then more skin must be taken from the lid than would otherwise have been necessary, and a slight degree of eversion of the centre of its edge produced, and which must necessarily have its limit. When it is apparent that such moderate eversion will not suffice, the treatment must depend on the degree of the trichiasis; if it be general, the entropion and it must be attacked by one operation. The cilia must be excised at the same time, that a sufficient extent of the skin of the muscle should be removed. But, when the trichiasis is partial—and, for the most part, it is—the muscle should first be dissected away, and then the irregular cilia removed. When there is doubt about the necessity of removing them, attend to the entropion alone, and observe the result, because it is not always possible before the operation for the entropion has been done, and the lid recovered from it, as well as from any inflammation and swelling that the entropion may have induced, to ascertain with exactness to what extent the trichiasis may be benefited. If, as is commonly the case, a patient applies to be treated for entropion, with many of the cilia broken, and some just about to be restored after having been plucked out, it cannot be known what direction they may assume when growing out; and such cases should be watched.

It can be very seldom that the removal of entropion from the lower lid does not at the same time separate any irregular cilia from contact with the globe, for a single exception only has occurred to me.

Our limits have not permitted us to give this paper in full, but the practical application of the reasonings contained in it seems to exist in the portion we publish. We, however, find no allusion to the operation for this distressing malady long ago proposed by Sir Philip Crampton, and which, if properly performed, most assuredly is effectual. If we recollect rightly, there is a paper on the subject by Dr. Jacob in the Dublin Hospital Reports: a book, although published some twenty years ago, seems never yet to have reached London.

**LUXATION OF THE SACRUM.**—An instance of this very rare accident is reported by M. Foucher in the case of a man who endeavoured to commit suicide by throwing himself beneath the wheels of a heavily-laden waggon. After death, which occurred at the end of a week, the chief appearance was, a dislocation of the sacrum forwards into the cavity of the pelvis. The ilia were also fractured. Similar cases are on record; one, for instance, in which the accident occurred from the falling of a sack of wheat upon the pelvis; and another is published by M. Laugier in the *Bulletin de la Société Anatomique*. In some other examples reported, the luxation seems to have been the result of disease.

OBSTRUCTION OF THE INTESTINAL TUBE—  
OVER-DISTENSION.

By Dr. OKE, Physician to the South Hants Infirmary.

OBSTRUCTION from over-distension may be caused by large evolutions of gas or by faecal accumulation; but although the former may occasionally obstruct the bowel, *per se*, by inflating it beyond the power of contraction, such inflations are more commonly the effect rather than the cause of the obstruction, the latter therefore will be principally considered in this place.

Obstruction, occasioned by faecal accumulation, generally occurs in some part of the large bowel, and it is probably produced in this manner:—The patient, from sedentary habits and a torpid state of the hepatic function, becomes costive, and every day, or every other day, has a dry insufficient stool. This goes on for some time, but as he is free from pain, does not feel ill, and has his usual appetite, he takes no particular notice of this state of his bowels, and does not deem it necessary to have recourse to any aperient, till at length, from the gradual accumulation of the faeces in the colon, he can pass no stool at all, and is seized with pain, vomiting, and all the symptoms of intestinal obstruction.

The diagnosis in this case will become sufficiently plain from its history; and by tracing carefully the course of the large bowel from the rectum to the caecum caput coli, we shall rarely fail to detect at what part of the canal the accumulation has taken place, where there will be fulness, tenderness, and dullness under percussion; but sometimes, doubtless, the diagnosis may be in some measure obscured by the inflation of the bowel.

The treatment of intestinal obstruction from this cause has to be conducted upon principles directly opposite to those indicated in the former. There the indication was to relax spasmodic action: here it is to excite the action of the bowel. When we have, by a careful examination of the symptoms, put ourselves in possession of the true nature of the case, it will be at first far better to endeavour to act upon the bowel through the rectum than the oesophagus. A good-sized, smooth, elastic tube, and well oiled, is to be gently carried up into the sigmoid flexure, as recommended by O'Beirne, and through it a copious enema of yellow soap and water is to be pumped into the colon, when the tube is to be withdrawn. It is necessary to use a full-sized tube, with a smooth bulbous end, which I would advise every general practitioner to keep ready for such a purpose. It will pass up the winding curve of the canal much more readily than a small one, and be less likely to perforate or damage the bowel.

I have seen many instances of the success of this practice, of which I will briefly relate one. A few years ago I was requested to visit the proprietor of a yacht in Cowes Roads, who was suffering from obstructed bowels. He was of middle age, and had been living incautiously. Mr. Davids, the medical gentleman in attendance, had adopted many judicious remedies for his patient, but without the desired effect. There was aching pain of the bowels and vomiting, and no stool had passed for two or three days; the abdomen was full, dull by percussion, and tender under deep pressure; but there was not much disturbance of the system. In consultation it was decided to throw up a copious enema into the sigmoid flexure by means of a long tube. Fortunately he possessed a capital one, which passed up admirably, and conducted the glyster into the gut. The remedy was crowned with success, and the patient recovered.

Sometimes our proceedings are stopped *in limine* by the rectum being stuffed with hard masses of faecal matter. If so, they must be removed by some convenient instrument till room be made for the tube to pass. A few hours after the colon has been injected in the manner above recommended, a purgative is to be given, and its kind must be governed by circumstances. If there is reason to think that the obstruction has been washed away, it will be sufficient to give four grains of the watery extract of aloes and three of calomel, in two pills every four hours, till they act; if not, the croton oil will be the best purgative,

of which one or two drops may be given in sugar or honey every two hours. If these means should fail to restore the action of the bowels, electricity and the sudden application of very cold water to the surface of the abdomen have been recommended. Of the former I cannot adduce any evidence from my own experience, although it would appear to be a most valuable remedy. The latter I have known to succeed.

H. R., a laundress in a gentleman's family, and unmarried, who had long been affected with valvular disease of the heart, was attacked in August, 1850, with subacute peritonitis, which was subdued by suitable remedies and by a very profuse hæmorrhage from the nose. On the 11th of September she was seized with severe pain of the abdomen, accompanied with constipation and vomiting. As the symptoms were urgent, I was requested to meet her medical attendant in consultation. I found her suffering severe pain on the left side of the abdomen, a little below the line of the umbilicus, where there was a fulness, painful under pressure. She was frequently sick, and the bowels still were obstructed. Her monthly secretion was present; there was no fever. It was agreed that two grains of calomel and half a grain of opium should be given every two hours, that a glyster (composed of half an ounce of the oil of turpentine, two drachms of the tincture of assafetida, one ounce of castor oil, and one pint of tepid gruel) should be thrown up the rectum every four hours, and that six leeches should be applied over the seat of pain. All this was attentively done, and various other extemporaneous means tried; but although the pain and vomiting had considerably subsided under this treatment, no relief was obtained from the bowels, which had now been constipated five days. By this time the abdomen had become somewhat inflated, there was hiccup, the pulse flagged, and her recovery was almost despaired of. Her medical attendant, Mr. Davies, supposing that the peristaltic action of the bowel might be suspended by over-distension, suddenly dropped upon the abdomen a towel saturated with very cold water, twice following, and then covered it with warm flannel. At the end of an hour the same thing was repeated; this was succeeded by frequent discharges of wind from the rectum, when the inflation subsided, and in a few hours the canal was copiously evacuated.

In this case, it is probable that the intestine first lost its vermicular power from faecal accumulation, and that it was afterwards still further incapacitated by the pressure of gas evolved from it. Such loss of power, the sudden application of cold in the above ingenious manner, was well calculated to restore; and it appears to have admirably succeeded.—*Prov. Jour.*

OBSERVATIONS ON THE SANITARY INSTITUTIONS OF THE HEBREWS AS BEARING UPON  
MODERN SANITARY REGULATIONS.By the Rev. ABRAHAM DE SOLA,  
Lecturer on Hebrew Language and Literature in the  
University of McGill College, Montreal.

(Continued from page 412.)

THE laws,\* too, have evidently not unfavourably affected their moral organization, for let us search the calender of crime of every country, and we shall be led to the conclusion that these same dietary and sanitary laws have had the effect of exempting them in a remarkable degree from that, to speak technically, plus-animalism or preponderance of the animal organs and instincts, which has led in others to the commission of the most awful crimes. In vain we seek their names in the long list of those convicted of inveterate drunkenness, of midnight plundering and assassination, of feticide, infanticide, of murder, and of other revolting and abominable crimes, which one dares not even think of or allude to. Of the correctness of this assertion it is easy to adduce evidence, but upon those who may feel disposed to doubt it, rests, as we imagine, the burden of proof to the contrary. It would appear also

\* In many parts of northern Europe the laws of the State permit only a certain number of Jews to marry.

that these laws have not had the effect of investing them with an inferior mental organization, for the attentive reader of history and observer of events, cannot but remain astonished at the immense, wondrous, influence they have exercised, and do even yet exercise upon the destinies of the world.\*—in the present day, more especially in the commercial and political world, though their influence and importance, religiously, as the ancient, preserved, and living witnesses of the Sinai revelation, is by no means to be underrated.† On this subject, however, it is not our province to dwell here, but we hasten to assure our readers that, in all we have said, we have not sought to assert that it is to their sanitary institution solely that the Hebrews owe their preservation as a people. Far from this. In

\* During the fatal prevalence of cholera in London in 1849, the editor of a leading paper thus writes:—"It is a singular circumstance, that throughout the late awful visitation, so few, if any, Jews died of the cholera in London, although the majority of them reside in districts where it committed great ravages." We believe that the authenticated cases did not exceed two, and one of these, personally known to us, was a gentleman of opulent circumstances, at Brighton, where he had gone for the advantages of sea air.

† Although we might adduce abundant proof of the correctness of this statement also, yet do we attempt to satisfy our readers and ourselves by simply quoting from one of the productions of the present Chancellor of England. Mr. D'Israeli, in his "Coningsby," thus writes:—"The Sarsen kingdoms were established; that fair and unrivalled civilization arose which preserved for Europe arts and letters, when Christendom was plunged in darkness. . . . During these halcyon centuries, it is difficult to distinguish the follower of Moses from the votary of Mahomet. Both alike equally built palaces, gardens, and fountains; filled equally the highest offices of the State; contested in an extensive and enlightened commerce, and rivalled each other in renowned universities." Sidonia, as a type, "was lord and master of the money-market of the world, and of course virtually lord and master of everything else; and monarchs and ministers of all countries courted his advice and were guided by his suggestions. . . . He had visited and examined the Hebrew communities of the world, . . . and perceived that the intellectual development was unimpaired. . . . And at this moment, in spite of centuries, and tens of centuries, of degradation, the Jewish mind exercises a vast influence on the affairs of Europe. I speak not of their laws which you still obey; of the literature with which your minds are saturated, but of the living Hebrew intellect. You never observe a great intellectual movement in Europe in which the Jews do not greatly participate." Mr. D'Israeli then at length shows how mighty revolutions are "entirely developed under the auspices of Jews," and mentions, as Jews, those who are or were professing Christians as excelling in theology—Neander, Benary, Wehl; in diplomacy—Arnim, Cancrin, Mendizabel; in war—Soult, Massena. "What are all the schoolmen, Aquinas himself to Maimonides? and as for modern philosophy, all springs from Spinoza." In music, "the catalogue is too vast to enumerate; enough for us that the three great creative minds, to whose exquisite inventions all nations at this moment yield—Rossini, Meyerbeer, and Mendelssohn—are of Hebrew race." Pastar and Grisi also! We cannot deny ourselves the pleasure of quoting also from a lecture on the "Unity of the Races," delivered by our learned and esteemed friend, T. S. Hunt, Esq., of the Canada Geological Survey, further evidencing the fact under notice, and as an excellent *resumé* of the above:—"We see the Children of Israel scattered over the face of the earth since eighteen centuries, without a country, yet finding a home in all; scorned and trampled upon, yet often the power behind the throne directing the destinies of kings; poor and abject, yet holding the golden keys of war and peace in Europe; excelling in philosophy and in theology, in music and in art, in war and in statesmanship; despised, yet ever powerful; counted as aliens, yet with their genealogies of forty centuries, looking down with scorn upon the aristocracy of Europe, which is but as of yesterday when compared with their own proud lineage, the Hebrew people still preserve all their natural characteristics, and stand proud and imperishable before us to-day, the representatives of the earliest ages of the world's history, and the evidence of the undying vigour of the pure Caucasian race."

common with all believers in the sacred volume, whether Christians or Jews, we witness the existence and preservation of Abraham's sons, and exclaim "the hand of the Eternal hath done this thing." Yes, we behold in it but the fulfilment of the predictions of their own lawgiver and prophets, the fulfilment of God's threats and promises to them. But in common with those believers, we are also impressed with the conviction that God frequently permits us to perceive and appreciate the means whereby He works out the end He proposes: that He as frequently prefers simple and natural means for the accomplishment of His behests, and that it is therefore quite permissible, after due inquiry, to maintain that the sanitary institutions of the Hebrews, have, under God, tended in a great measure to secure the present preserved and undeteriorated existence of the nation. To what extent they have done so it will of course be for the reader hereafter to decide. Believing, as we have already affirmed, that it is to a very great and important extent, we think no further introduction or apology necessary, ere we introduce them, as we proceed now to do, to these sanitary laws and constitutions themselves.—*Canada Medical Journal*.

(To be continued.)

#### REVIEWS AND NOTICES OF BOOKS.

THE SYMPTOMS AND TREATMENT OF THE DISEASES OF PREGNANCY. By W. J. ALDERSON, F.R.C.S., District Accoucheur to St. Mary's Hospital. London. 1852. 8vo. pp. 119.

WHEN a practitioner publishes a book, it is to be supposed that his object is either to supply a want in professional literature—to make known something original, or else something in the way of compilation that may prove useful. In none of these respects, however, has the volume before us any pretensions, and in completeness it falls short of many of the standard treatises upon the subjects to which it relates. We are, therefore, quite at a loss to discover what could have induced Mr. Alderson to appear before the public as an author. Not that the book is badly written, or contains unsound doctrines, or erroneous opinions, but that there is positively so little information in it. In the description, the pathology, and the treatment of the several diseases of pregnancy, it gives a mere outline—useless to the practitioner—insufficient for the student. But as it would be a most extraordinary book from which some piece of information, theoretic or practical, could not be gleaned, so it must be confessed that this volume has supplied us with two or three new ideas. In the following physiological observations may be found one or two novel points:—

"It has been before stated that during pregnancy there is a state of moderate general plethora. There being under the circumstances, a greater demand for blood, there is also a tendency to the formation of an increased supply of that important fluid. Now, in plethora, there is an excess of the red globules of the blood, which contain a compound of iron, having a strong affinity for oxygen, which gas is absorbed by them from the atmosphere in the lungs, passes to the heart, and is thence distributed to the whole body. In the systemic capillaries, the globules part with their oxygen and acquire the power of combining with carbonic acid, during which process animal heat is evolved. The amount then of animal heat is very much regulated by the quantity of the red globules contained in the blood; and as all changes in the nervous system occur where its fibres come into relation with the vascular plexus, it follows that this system must be more or less affected by an abnormal increase of the red globules; the force of the circulation is augmented; the heart's action is increased by receiving blood too stimulating in its character on account of the excess of oxygen which it contains; and the nervous system being thus supplied with blood superabundant in quantity, and of an improper quality, has its power greatly augmented; and acting in this state secondarily upon the whole circulating system, it supplies a morbidly increased amount of nervous influence, and thus keeps up the excited state of the circulation."

Among the "affections of the uterus and its contents" is

one which has hitherto escaped the attention of nosologists, and of writers upon midwifery—viz., “fœtal turbulence.” To what order or class this should be referred in any system of nosology, would puzzle Sauvage, Cullen, or Good. Its symptoms and treatment are thus described by Mr. Alderson:

“Occasionally the motion of the fœtus in utero becomes so violent as to be truly distressing to the mother. A sense of sickness, attended often with local pain, and much general nervous agitation, is induced. This affection may depend upon some preternatural sensibility of the uterus itself, but the more probable cause appears to me to consist in a state of general nervous irritation, which, from the condition of the uterus at this particular time, is more especially determined to that organ. The bowels should be opened by laxatives, and a very small quantity of blood abstracted, if the symptoms are sufficiently strong to warrant it. The administration of sedatives is often attended with great benefit, and mechanical compression, by means of an abdominal bandage, will frequently prove to be of much service.”

These extracts will serve to show the author's style of composition, which is by no means bad or incorrect; in fact, all the work wants to make it a good and useful compendium is a little more *matériel*—somewhat more of substance and strength. This is its great fault, but it is only a negative one, and in our estimation renders the book far less objectionable than many of the distinguished treatises of the present day, which are, no doubt, full of information and statistics, but abound also in dangerously plausible hypotheses, and unsound practical deductions.

## MEDICAL PRESS.

“SALUS POPULI SUPREMA LEX.”

DUBLIN: WEDNESDAY, JULY 7, 1852.

### KEEPING OF THE DISPENSARY BOOKS.

WE receive conflicting reports respecting the difficulties experienced in the filling of the blank returns furnished from the Poor-law Office. The following having reference to the subject, we print to elicit more information:—

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—We all trusted there would have been some very considerable modification of the book-keeping system; so you may well fancy our disappointment at finding that this part of our labour has been increased tenfold within the last month. It is ordered that there shall be on the counter of each dispensary a tray with three compartments, the first of them to contain a bundle of prescribing papers. When a ticket is presented, it is first to be entered in the register; then you paste one of the prescribing papers to the back of the ticket; then at the top of the ticket, and also on the prescribing paper, you mark the day of the month, and the number in the register; you write also the same on a small detached piece of paper; on the prescribing paper you enter every day the patient comes and the medicines you give. The detached paper you give the patient, to be produced every subsequent day medicine may be required, to facilitate the finding of the ticket. The ticket is then to be placed in the second compartment of the tray. If a patient should be absent for a fortnight, the ticket is then to be shifted to the third compartment.

Such are the orders the surgeons have received in some of the unions of the county of Cork. I believe it is not a general order, but yet confined to the district of perhaps one inspector. It is represented that the object of it is to be able to account to the guardians for the medicines used.

Just fancy a man with one hundred tickets in the second compartment of his tray, shuffling them every time a patient presents himself, and occasionally going through as many more in the third compartment! You will at a glance see what a sacrifice of time and labour a compliance with this order would involve; and it is just simply absurd to think it could be turned to any useful account. How many tickets would you have to shuffle to account for a few drachms of croton oil, an ounce of calomel, or a pound of chamomile flowers? Lest I should not have explained myself sufficiently clear, I send you a ticket and the two papers marked as directed.—I remain, dear sir, truly yours,

ONE OF THE SUFFERERS.

### UNIVERSITY REFORM.

WE had the following in print when we received the Report to which it refers, and we insert it as an abstract of that Report, adding in full the paragraphs which bear on the question of the rights of Medical and other Graduates of high standing to a voice, by representation or otherwise, in the regulation and government of the Universities to which they belong. It gives us much satisfaction to find this subject every day more and more attracting attention. As places where a proper preliminary education should be afforded to candidates for admission into our profession, these Universities come legitimately within the province of the medical journalist, and still more as places where medical degrees (accepted by usage as qualification to practise) are granted. We therefore propose to return to the subject from time to time until we make our readers acquainted with the true nature and value of these institutions and the gross abuses which prevail in them:—

The committee appointed by the senate of the University of London to take into consideration the letter of Mr. Secretary Walpole, and all documents connected with the claim of the graduates to incorporation, have prepared a report, which has been presented to the senate. The senate have postponed the consideration of this important report till after the next meeting of parliament. We understand that the following are its leading features:—The committee glance at the constitution and objects of the older universities, for the purpose of estimating how far they bear upon the position of the University of London. They refer to the limited powers of convocation in the case of the older universities. They conclude that the claim of the graduates of the University of London to participate in its government rests upon different grounds. To the first proposal, that the body corporate shall consist of the chancellor, vice-chancellor, fellows, and graduates, the committee see no objection; and so far as it would facilitate the grant of the parliamentary franchise and a representation in the House of Commons to the graduates, they give it their cordial approbation. They remark, that as the number of graduates increases at the rate of more than eighty every year, the members of convocation must soon become very numerous. They are apprehensive that a convocation such as that which is proposed by the committee of graduates would not be desirable; but anxious to meet the wishes of the graduates, whom they represent as being animated by a desire for the personal dignity which is associated with the performance of active and honourable functions in the service of the university, they express a hope that a convocation of a more limited number, and with more definite purposes and powers, may afford a means of tranquil and effective manifestation. They accordingly recommend the creation of a convocation consisting of all the masters of arts, of all who have been, are, or shall be university scholars, and of the senior half of the doctors in medicine and the senior fifty graduates in law. They recommend that the convocation meet twice a year, that it receive communications from the senate, and address to them any suggestions and observations which it may think advisable. The committee object to the proposal of the graduates that they should have the power of submitting to the Crown, lists of persons from whom a certain proportion of all future fellows shall be elected, chiefly upon the ground that the university is mainly supported by the State. They think, however, it would be advisable to suggest adding to the senate three graduates forthwith. We leave these heads for the present to the consideration of the graduates and of the public, congratulating them upon the liberal spirit in which the senate have entered upon the great questions involved; and not doubting that when the senate meet again for the serious consideration of this report, they will be prepared to entertain with equal liberality the suggestions that will assuredly be offered them, with a view to the improvement of the scheme of their committee, and the perfection of the constitution of the metropolitan university.—*Lancet*.

Extract from a Report presented by the Committee of the Senate appointed to consider this matter. The Committee consisted of the Chancellor (Lord Burlington), the Vice-Chancellor (Mr. Shaw Lefevre), Lord Monteagle, Sir

J. Graham, Mr. Grote, Dr. Arnott, Mr. George Cornewall Lewis, and Mr. Senior:—

The bulk of the graduates are allowed a very small share in the management of the affairs of the older universities, deeply as they may be affected by it. The convocation itself is permitted to exercise the powers which it possesses only under narrow restrictions. It considers only the matters submitted to it by the governing authority, cannot discuss them except in Latin, and cannot propose an amendment. It can simply accept or reject.

We now proceed to consider the alterations in the constitution of the university which have been submitted by the committee of graduates to the senate, and have been referred by the senate to us.

The first proposal is, that the body corporate shall consist, not as it does now, of the chancellor, vice-chancellor, and fellows, but of the chancellor, vice-chancellor, fellows, and graduates.

To this we see no objection; and so far as it would facilitate the grant of the parliamentary franchise and a representation in the House of Commons to the graduates, we give it our cordial approbation.

The second proposal is, that the graduates of a certain standing should have the right of meeting in convocation, to be called together by persons appointed by itself; and the power of regulating the place and times of its meeting, and its own proceedings; and the right of discussing any subject, and of recording its opinion thereon; but with no power of interfering with or annulling any acts of the senate, except in the cases of surrendering or accepting a charter.

The necessary standing of the members of the proposed convocation is not absolutely defined; but the reference in the Observations to the analogy of the masters of arts in the older English universities indicates a standing of three years, that being the interval in Oxford and Cambridge between the bachelors' and masters' degrees.

As the number of graduates increases at the rate of more than eighty every year, the members of convocation would soon become very numerous.

It appears to us that a large body meeting at pleasure, with no legislative or administrative functions, whose whole powers and whose whole duties would be to discuss and to adopt resolutions, would not be likely to act beneficially on the government of the university. We cannot, therefore, recommend the creation of a convocation such as that which is proposed by the committee.

But we are anxious to meet the wishes of the graduates. We believe that in the present petition they are animated by a genuine interest in the continued success of the university, and by the desire of the personal dignity which is associated with the performance of active and honourable functions in its service. These are sentiments which, far from reproving or discountenancing, we desire to encourage, and to which we shall be glad to afford a means of tranquil and effective manifestation; and we hope that this may be done by means of a convocation of a more limited number, and with more definite purposes and powers.

We recommend that the senate propose to Mr. Secretary Walpole the creation of a convocation consisting of all the masters of arts, of all who have been, are, or shall be, university scholars, and of the senior half of the doctors in medicine, and the fifty senior graduates in law.

This would afford immediately a body of about 160 persons annually, and quickly increasing, which would include the most distinguished of the graduates, and from which no one capable of taking the degree of master of arts would be excluded.

We recommend that the convocation meet *de jure* twice a year, with power at each such meeting to adjourn once only; that it receive communications from the senate, and address to them any suggestions and observations which it may think advisable.

We recommend that the senate be empowered to summon, whenever it thinks fit, an extraordinary meeting, and be required to do so on the occasion being pointed out by the committee of graduates—the surrender or acceptance of a charter—and that in such extraordinary meetings the convocation discuss only the propositions submitted to it by the senate; and we recommend that the surrender or acceptance of a charter be the only act as to which the concurrence of convocation, either in its ordinary or in its extraordinary meetings, be necessary.

Such a change in our constitution would connect the graduates permanently with the university; would constitute

them an integral part of the corporate body with some functions, honourable though not extensive; would enable them twice in every year to express all their opinions and all their wishes on every subject connected with its management; would render their concurrence in every modification of its charter necessary; would enable their opinion to be taken as to every other matter which the senate should think it right to submit to them; and probably would be a further step towards their obtaining a parliamentary franchise.

## CORRESPONDENCE.

### CASE OF RETENTION OF URINE.

TO THE EDITOR OF THE MEDICAL PRESS.

MY DEAR SIR,—I really do not see why my perfectly fair and legitimate notice of Dr. Lynn's case should have provoked the intemperate and personal reply it has done—a reply for which he has not even the insufficient excuse of hasty composition, as “the mountain” which produced this “ridiculous mouse” has been three weeks in the throes of ■ evidently unnatural labour.

I noticed the case simply because it might have been supposed (and literally was inferred) that, as the Infirmary Surgeon of this county, I had “coöperated” in the treatment pursued; and secondly, because *malgré the bad taste*, and all the other hard names which have been applied to my conduct, I considered it my duty (and shall ever so consider it) to endeavour to vindicate Sligo surgery from the ridicule and opprobrium in which the unanswerable publication of such cases would, most justly and properly, involve it.

As there is not one word of refutation of my critique in the letter alluded to, I might leave the case as it stands, merely reminding Dr. Lynn and your readers of the *slight dialectic non sequitur* of his proposition—the patient recovered: ergo the treatment was proper.

But I cannot permit the eminent authority (Mr. Fergusson) to be forced into standing silent sponsor for a treatment which, so far from recommending, he explicitly condemns. Dr. Lynn having misquoted me, naturally ends by misunderstanding Mr. Fergusson. It is quite true that this eminent surgeon advocates forcible catheterism in certain cases. But what are they? Those cases, and those alone, in which “the obstruction is seated near the neck of the bladder” (see “Fergusson's Surgery,” Ed. 1842, pp. 545 *et seq.*); not surely in the case of a urethra through which a catheter had been “frequently” and “with facility” passed, and through a false passage, “commencing,” in Dr. Lynn's own words, “so near the orifice.” I would also refer Dr. Lynn and your readers to a most interesting discussion (see MEDICAL PRESS, May 12, 1852), by the London Medical and Chirurgical Society, on Mr. Cock's paper, on “Surgical Operations for Retention of Urine,” in which, among the following leading professional names, I do not find *even one* recommending the practice under almost any complication of urethral obstruction—namely, Messrs. Cock, Solly, Arnott, Coulson, Curling, Gay, Hodgson, Hewett, Hawkins, and Ward. Sir Astley Cooper never even alludes to such a measure; nor any other surgeon, even of the heroic French school, with whom I am acquainted, under the circumstances of Dr. Lynn's patient.

It is unnecessary to allude to the other irrelevant topics of Dr. Lynn's letter. That the great majority of these and all other surgical cases (in the proportion of perhaps 99 to 1) pass through my hands, I reassert as a notorious fact too well known to be contradicted. Dr. Lynn's allusion to our misunderstanding (*quarrel* is an ugly word, and it so happens that in fifteen years' practice, I never had a single misunderstanding with any medical gentleman whomsoever on a subject purely professional), his allusion, I repeat, to these unfortunate matters, which it were well not to advertise in the pages of the MEDICAL PRESS, and which I sincerely deplore, is injudicious for himself in the extreme, at a period when the ink is hardly dry on the paper which expresses his public apology, awarded to me upon the arbitration of five of the most respectable gentlemen in this neighbourhood.

As I share, in common with all the great professional names of the day (whom we never find pleading want of time for much more voluminous compositions than Dr. Lynn's half dozen lines in the MEDICAL PRESS), the blessing of plenty of leisure, I shall devote a little of it to expose fully any future attempt to misrepresent my motives, or to embroil me with my professional brethren, as this letter seeks to do—a course of conduct of which a very recent signal failure should have taught him the impolicy and futility.—I am, my dear sir, faithfully yours,  
WM. S. LITTLE, A.B., M.B., &c. &c.

Sligo, June 30, 1852.

## ADULTERATION OF DRUGS.

Most persons, we admit, can judge very correctly by sight of the quality of most articles of food and clothing; but where is the man who can, by simply looking at the almost countless number of medicinal preparations, chemical and otherwise, say whether they are pure or adulterated? or by looking at the various preparations of morphine, say whether they do or do not contain five, ten, or twenty per cent. of *amygdaline*? or can detect, by sight, *corrosive sublimate*, *prepared chalk*, *gypsum*, and other impurities in calomel? or can, by sight, say whether blue-pill mass contains its full equivalent of mercury, or only one-fourth, or less, of the requisite quantity? or can say whether hydriodate or iodide of potash is pure, or is adulterated by the admixture of *sal acetosella*, *sup. tartrate*, and *sulphate of potash*? or can, in the same way, detect *salicine*, *mannite*, *sulphate of barytes*, and *oxyde of zinc*, in sulphate of quinine? or can say whether croton oil is, or is not, adulterated by the admixture of inert fat oils, or whether it is not, in fact, an entirely *fictitious article*? or by looking at the powdered cinchona bark, say whether it is genuine powder of that species which affords the largest quantity of quinine and some cinchonine, or whether it contains thirty or fifty per cent. of the powdered *Maracaibo* or *Carthagera* bark, which affords but a trace of either of these important alkaloids, and is consequently worse than worthless for medicinal purposes; or whether it is not, in fact, composed *entirely of the latter worthless variety*? or can say, by looking at powdered rhubarb, whether it is of that prime quality which affords from sixty to seventy per cent. of soluble matter, and some twelve per cent. of pure resin, or whether it is an article produced from the *decayed and worthless root*,—the colour and smell having been heightened by artificial means,—which affords not to exceed fifteen per cent. of soluble matter, and *no resin at all*?

The several barks before alluded to, although differing in physical appearance, are those generally known in the trade as the red and yellow *Maracaibo* and *Carthagera* barks; and as they resemble the true officinal bark in colour, they have long been used in a powdered state for the purpose of adulterating those barks, or sold to the unsuspecting as a genuine article. This fact shows very clearly why it has long been almost impossible to find on sale, in the country, or even in any of our minor drug and apothecary establishments in town, one pound of the red or yellow cinchona bark of the requisite strength and purity; or, in other words, that will afford, on analysis, a per centage of alkaloids corresponding with that produced by the genuine barks. Some samples that have been obtained afforded neither quinine nor cinchonine in any perceptible quantity! others, less than one-fourth part of the alkaloids found in the true and pure barks; and so upward, according to the extent of the adulteration. From the quality of samples that have been forwarded to me from a distance, I am satisfied that the country is filled with such base mixtures and worthless trash.

The question now very naturally and properly comes up, will prime crude drugs, after having been powdered and prepared, be found on sale, in town and country, in as pure a condition as when imported? or, in other words, be found free from adulteration? I fear not, unless a strict watch is kept over the operations of the *unprincipled* portion of those among us, whose mission it is "to buy, sell, and get gain," honestly, if they can; if not, get it.

It has heretofore been too frequently found that drugs become astonishingly reduced in strength and purity during their transition state, from root, bark, gum, &c., to powder. Prime fresh drugs are, no doubt (as well as worthless), sent to the drug mill; but somehow or other, "by falling into bad company," I suppose, they are apt, during their stay, to lose their virtue; and, as a matter of course, are returned to their owner, and sent out into the market, with a character decidedly tarnished—an article fair to look upon, but whose touch is death. Badinage apart—the business of drug-grinding or powdering requires a searching and thorough reform.

I have already alluded to the mysteries and trickery of the laboratory when in skilful but dishonest hands; but, be assured, its conjurations and diablerie, if I may so express myself, in the preparation of adulterated chemical medicinal compounds, hardly exceed, in ingenuity, deception, and iniquity, the frauds committed under the roof of the drug-mill.

I have in my possession the voluntary confessions of a drug-grinder, who has retired after amassing a fortune in the business; but I will not swell this report by entering, at this time, into an extended detail.

This is a very important subject; and one, too, which the profession throughout the country, as well as the medical staff of the army and navy, whether on duty at a distance, or at home in hospital practice, should lose no time in investigating; for how is it possible for the physician to do justice either to his patient or himself, however judicious and correct his prescriptions may be, as long as there is so much uncertainty as to the strength and purity of the curative agents he may recommend? I cannot but believe that many, very many, valuable lives have been lost, owing to this lamentable condition of things.—*United States Med. Examiner.*

## ABSCESS OF THE SUBSTANCE OF THE UTERUS, OPENING EXTERNALLY.

By Dr. VAN COURTLAND.

ON the 27th of June, 1830, the author was sent for to see W. M., aged 24, who told him she had been delivered of a living child about two months previous, but had never left her bed, owing to a swelling in the lower part of her belly, and which began to show itself a few days after her confinement. The patient was emaciated to a most extreme degree, and was labouring under profuse and almost uninterrupted perspiration. The pulse was small and rapid. The countenance indicative of serious disorganization. The secretion of milk was entirely suspended. The lochial discharge had left her a few days after parturition; and the spirits were painfully depressed. On examining the swelling, owing to the great emaciation, he readily discovered it to depend upon an abscess of the body of the uterus; adhesion between which and the abdominal parietes had taken place during the inflammatory state, and the abscess now in progress clearly indicated the plan of treatment to be adopted. Large doses of diluted sulphuric acid were given without producing diarrhoea, warm fomentations and emollient poultices were applied to the tumour, and frequently renewed until the 8th of July, when a free opening gave vent to about half a teacupful of matter. From this time, everything went on well, and in a few days she returned home cured. Her catamenia have come on regularly, but as yet she has not again become pregnant. In cases of this description, the discharge of matter almost invariably takes place by opening internally either into the bladder, rectum, or vagina.—*Canada Medical Journal.*

**FECUNDITY OF A FREE-MARTIN.**—Dr. Joseph Moore of the Jefferson Medical College, U.S., communicates the following to Professor Dunglison:—I herewith forward you a newspaper, published in the town where I reside, in which a communication from a very intelligent farmer, relating to a free-martin which he raised on his farm, and which not only received the male, but gave birth to a healthy offspring. The gentleman who is the author of the communication, I have known for several years, and can therefore vouch both for his intelligence and veracity. As a knowledge of such cases is not devoid of interest to persons devoted to scientific pursuits, a perusal of the paragraph may be gratifying:—

"*A Nut for the Curious.*—On the 5th of June, 1849, one of my cows dropped two calves, a male and female, and on the 11th of October last, the latter dropped a calf, healthy and strong, and has the appearance of making a good cow. I have never heard of a similar instance.—B. SHEPPARD."

This case disproves the correctness of the commonly received opinion that the female of twin calves is invariably barren and unfruitful.—*Phil. Med. Examiner.*

**AMAUROSIS PRECEDED BY HÆMATEMESIS.**

T. B., aged 50, labourer, father of several children, of quiet and temperate habits, was seized while at work with a sudden attack of hæmatemesis, and ejected from the stomach full three pints of dark-clotted blood, without the slightest pain or uneasiness. He was taken home, and I saw him within an hour of the attack. He appeared cold and cadaverous, and to all appearance in articulo mortis. I put him on the antiphlogistic treatment. He continued, however, for several days, and at short intervals, to eject small quantities of dark, grumous, semi-sanguineous-looking matter; and notwithstanding every effort, the poor man became, and has continued up to this time, completely amaurotic. As a matter of course, considerable debility followed, which was attended to in the usual way. I may here observe, that when he became convalescent, he took the advantage of London advice, and was recommended to the Eye Institution at Moorfields, where the treatment was merely a repetition of what had already been done. The poor fellow returned, and is now to be seen daily reconnoitring in our streets, guided by one of his children, and in total oblivion to the light of this glorious creation.—*Mr. O'Reilly in Lancet.*

## PROCEEDINGS OF SOCIETIES.

### SURGICAL SOCIETY OF IRELAND.—MAY 1.

Mr. TRANT, President of the College, in the chair.

DR. BANON brought before the notice of the Society on this evening a very remarkable instance of

#### LATERAL HERMAPHRODITISM

in the human subject, which he had met with some months previously, and exhibited the preparation and also some beautiful drawings and casts, showing the external malformations and also the internal organs of generation as they appeared on dissection.

The subject of the case was a convict named Andrew R—, who had been sentenced to seven years transportation, as a male, for sheep stealing, at the Ballyconnell sessions, in April, 1848. He was thence transferred to the Richmond Government Prison, of which Dr. Banon is the physician, and afterwards to the Mountjoy Prison, where he remained from the 16th of December, 1850, to 14th of April, 1851, when he was again sent to the Richmond Prison, being unable from illness to undergo any longer the severer discipline of the former. He now, for the first time, came under Dr. Banon's observation, and was admitted by him to hospital on the 15th of April, 1851, with symptoms of phthisis, which disease proved fatal to him in the October following.

Dr. Banon did not become acquainted with the sexual peculiarities of this individual until shortly before his death, owing to the strong disinclination which he had to their being known, even to those most intimate with him.

Dr. Banon ascertained, however, that at his birth there was considerable doubt as to the predominant sex of this individual, but that at length it was pronounced to be a female, and baptized by the name of "Anne." In a year subsequently, however, the organ representing the penis had so increased in size that a different conclusion was arrived at, and the name changed to "Andrew," since which period he had been always treated and looked on as a male; and as he grew up, even excelled in many of the manly exercises. His predilections were, according to his

own statement, for females, and it was ascertained that he had never menstruated.

Dr. Banon gave a full and minute description of the external and internal organs of generation which were present in this individual, by which it appeared that he possessed a penis of the usual size in the male adult, and provided with glans and prepuce, but that it was imperforate, a rudimentary opening only existing in the site of the orifice of the urethra. The individual had himself stated that it was during life subject to erections. On raising up the penis, Dr. Banon observed that the female external organs were present in a nearly perfect condition. The labia were well marked, but terminated behind rather abruptly, the fourchette being absent. Within these the nymphæ were seen occupying their usual situation, and between them there was a longitudinal opening which led directly to the bladder. Behind this urethral opening was observed one of a more circular form leading to a canal in the direction of the uterus, and separated from the bladder in front and the rectum behind by distinct septa. This orifice was so small as to admit only of a No. 8 catheter, and was surrounded posteriorly by a distinct hymen. The mons veneris was not developed, which might have been owing to the great emaciation present. Many of the secondary characters of the male were observed. The hair, arms, hands, lower limbs and feet, the larynx, all partook of the male character. The voice during life was decidedly masculine.

On the other hand, there was a feminine character in the features of the upper part of the face, and the pelvis and skull were decidedly those of the female. The occipital regions of the latter were unequally developed on each side, which point was dwelt upon by Dr. Banon as illustrating, in this instance, the interesting physiological fact, that the development of the reproductive organs is influenced by this portion of the brain, these organs being, as he afterwards pointed out, situated principally on the side of the body opposite that of the increased development in the posterior lobes of the cerebrum and cerebellum.

On dissection, the penis was found to be composed of

cruræ, uniting in the usual manner to form the body. A substance, similar to the corpus spongiosum urethræ, could be traced anteriorly to the glans, and behind becoming bifurcated to enclose the longitudinal opening leading to the bladder. The prostate and Couper's glands were absent. The spermatic cord on the right side was large. On the left, it rather deserved the name of the round ligament of the female.

On dissecting the parts within the pelvis, a well-formed but small uterus was found in its normal position between the bladder and rectum. It was supplied with but one Fallopian tube, which passed from its left cornu backwards and inwards, between the rectum and uterus, to the right side of the latter, where it terminated in a well-marked "corpus fimbriatum," being permeable throughout its whole course.

The corpus fimbriatum rested on an ovary which, as well as the Fallopian tube, was single, no trace of a second being visible. Not far removed, however, from the ovary already mentioned, was observed a testis, pendulous into the true pelvis, in front of the right sacro-iliac synchondrosis, and immediately behind the internal iliac artery, as it descends into the pelvis. Applied to its anterior surface was seen the epididymis in a partially unravelled state, and the spermatic artery and vein were traced into close connexion with it. The vas deferens was plainly seen emerging from the epididymis, and taking a remarkable course—at first, forwards and outwards, in the direction of the right internal abdominal ring, to which it had reached about half way, when it turned back, forming a loop, with the convexity towards the ring: it then took its course inwards and somewhat backwards, in the direction of the uterus, to which it was finally conducted by the broad ligament of the right side. It could be traced into the substance of the uterus, into the cavity of which Dr. Banon proved that it opened by pressing mercury gently through it. Dr. Banon could not find any trace of vesiculæ seminales, nor of a second testicle. Dr. Banon here gave a minute description of his dissection of the different organs, and of the appearances of some of them under the microscope, which enabled him to speak with confidence of their identity. He then entered at some length into the discussion of the means of discriminating between the spurious forms of hermaphroditism and those which are entitled to be considered as a real blending together of the reproductive organs of both sexes, or the "true hermaphroditism;" and cited some remarkable cases, both in the human subject and the lower classes of animals, in which both forms had been observed. In the present instance he came to the conclusion, that it should be placed under the division of "true hermaphroditism," termed "lateral" by Professor Simpson. Dr. Banon also alluded to some of the most interesting of the physiological changes which take place in the earlier development of the embryo, and explained how an error of function at this period in the corpora Wolffiana, by which both the male and female reproductive organs, the testes and ovaries, are originally formed, would be likely to cause subsequent anomalies and malformations to appear. He also entered into the question—How far the conditions necessary for self-impregnation were present in the case of Andrew R.—? And although he was obliged to admit that were the testis by any means so excited as to cause its secretion to pass through the vas deferens into the uterus, there was nothing to prevent the semen from proceeding farther, through the Fallopian tube, to the ovary; still, from the absence of the procreative elements (the spermatozoa) in the seminal fluid, as proved by the microscope, and also of the germinating elements of the ovary, self-impregnation in this instance could not have occurred. Dr. Banon concluded a highly interesting paper by stating that it was his intention to publish it in full, and bring it before the profession in a form rendered complete by the addition of lithographic plates of the drawings and casts which he had now the pleasure of exhibiting to the Society.

Dr. BEATTY observed that the Society were greatly indebted to Dr. Banon for the careful manner in which he

had laid a case of unusual interest before them. The details had been set forth with a degree of accuracy and precision but seldom attained in a case of so much importance; and from the description of the external, and the very careful dissection of the internal organs, there could be no room whatever to doubt that it was a case of lateral or vertical fusion of the organs of generation. It was not a case of spurious hermaphroditism, but it was evidently a case of genuine fusion of the generative organs of both sexes—a condition much more rarely met with than cases of spurious hermaphroditism. Amongst the casts which Dr. Banon had placed on the table, as illustrative of some of the forms of spurious hermaphroditism, was a case of malformation, where the parietes of the abdomen were deficient—where the bladder terminated in a cul-de-sac. How a case of this kind could give rise to a suspicion of doubtful sex he was quite at a loss to conjecture, for there was nothing in the appearance of the parts to warrant such a suspicion; nevertheless, it had been set down in works on hermaphroditism as one of the sources of doubtful sex. He recognized another of the casts on the table as an old acquaintance. It was one which he (Dr. Beatty) had the honour of presenting to the College of Surgeons, and was taken from a patient of his own. He referred to it now because it was set down in books as an instance of hermaphroditism, whereas, in point of fact, it was one of acute prolapsus of the uterus, where, by the sudden prolapse of that organ, the vagina became suddenly inverted, and assumed the appearance of an enormously dilated penis, shortened in its transverse diameter, yet resembling a penis in a state of extreme distension. A person afflicted with this disease was exhibited in London, several years ago, as a hermaphrodite, and it was reported that a sum of £400 was speedily extracted from the wondering public. Any person conversant with the condition termed "prolapse of the uterus," would, however, at once recognize that case as simply an example of what was called "acute prolapsus of the uterus," where the organ was suddenly forced down, the vagina inverted, and the previously red coat of the latter exchanged for a species of cuticle. Dr. Banon had quoted in his paper some remarkable instances of true fusion of the sexual organs, taken from a valuable article written by Dr. Simpson in the "Cyclopædia of Anatomy and Physiology" several years ago. He (Dr. B.) would take the liberty of reading for the Society an extract from a paper on the same subject, written by himself, and published in the "Cyclopædia of Practical Medicine" some time previous to the appearance of Dr. Simpson's valuable essay. The case was this:—In April, 1807, an individual was exhibited in London, uniting the organs of both sexes in the highest perfection, perhaps, ever seen. The person was 28 years of age, and possessed of the male organs. There was a penis, or what represented one, capable of erection, covered with a prepuce, and perforated, for a third part of its length, by a canal. The testicles were also present; the hair and features were masculine, and a light beard covered the chin. The female organs, represented by the labiæ, vagina, and vulvæ, were very small. The individual menstruated regularly, and had been twice pregnant, but was prematurely delivered on each occasion; first at three, and then at five months." This case, if the description was correct, was the nearest approach to a true hermaphrodite ever met with in the human subject. Having heard that Dr. Banon had intended to bring the subject of hermaphroditism before the Society, he thought it would be useful to mention that case as a corollary or addendum to his valuable communication.

Dr. POWER said that Dr. Banon had been aware of a case which, a short time since, came under his (Dr. P.'s) observation, and which, to a certain extent, resembled the one he had laid before the Society on that evening in his truly valuable communication. It was Dr. Banon's wish that he should refer to the notes which he had taken of this case, and in conformity with that expressed wish, he would trespass for a short time on the attention of the Society. The case was, beyond a doubt, one of herma-

phrodisms. He remembered, on the evening of the 15th of January, 1851, being called on by a lady to go and see her sister, as she called the individual; he remembered going with her, and that when he arrived at the house, he met a very respectable practitioner from the country, who was in ordinary attendance at the time. He told him (Dr. P.) in private, that he had a fact to communicate which he thought the family themselves were aware of—namely, that the patient was a hermaphrodite; and, he added, that the disease under which this person laboured was strangulated inguinal hernia of the right side. The age of the individual was 62, and the person was unmarried. On examination he found a distinctly developed penis, which was, however, of a rather small size; and, on turning to the right side, which was the seat of the inguinal hernia, he observed that the tumour, which he took to be an intestine, had passed down into the right labium; and on examination still further he found that, besides the penis, there was both a right and a left labium, the former being extremely large, and the latter a good deal smaller; and between these was a distinct fissure, resembling the appearance which a bifid scrotum might be supposed to present. He next directed his attention to the extremity of the penis, where he found a distinct prepuce, a distinct glans, and a distinct orifice of the urethra. Two tumours were discovered in the right labium, and, on percussing the upper one, he felt satisfied that it contained a piece of intestine. The symptoms were a tympanitic sound on percussing the upper tumour, pain on pressure, vomiting, and all the other circumstances which indicate strangulation of the intestine. On examining the lower part of the tumour, he found a solid body, the existence of which he was for a while at a loss to account for. This solid body was of large form, and resisting. Pressure on it produced a peculiar sensation, totally different, in the patient's feelings, from the sensation experienced by pressure on the upper tumour; and between the two swellings there was a decided constriction, so that the whole mass presented very much the appearance of an hour-glass; that is to say, there was an evident constriction near the centre, with one enlargement above, and a second smaller one below; the latter being, as he thought, a testis in a state of inflammation. On feeling the labium at the left side he could perceive a small tumour within it, and a cord leading from it upwards, towards the groin of the left side. The size of this body was not much larger than a sparrow's egg; and what struck him as most remarkable about it was, that when he gave it a squeeze a sensation was experienced by the patient similar to that which was felt on pressing the lower tumour at the opposite or affected side. The symptoms of the strangulation were not extremely urgent; but, under all the circumstances of the case, he thought it better to have a consultation before proceeding with the operation. The benefit of Mr. Adams' opinion was procured—the operation was determined on. Dr. P. cut down on the tumour, laid it bare, and thus ascertained the existence of a portion of intestine in the upper part in a state of strangulation; and in the lower part, a testicle with its epididymis. The narrowed condition of the parts between the two tumours was not produced by the intervention of the lower portion of a sac, separating the tunica vaginalis from the intestine; but it appeared rather to be a constriction which existed in the centre of the common tunic. On exposing thus the contents of the right labium, they were found to consist of a congenital hernia, formed by intestine, in a state of strangulation, in the upper part; and of a well-formed testicle in the lower. The stricture was divided, and the intestine returned, but the individual did not recover, having lived for eight days only after the operation, and without any discharge taking place from the bowels during that interval. He regretted exceedingly that he was not permitted to make an examination of the body. Indeed he was not surprised to find the other members of the family preferred to resist everything like an examination. One of the ladies told him privately that her "sister," during life, was a very

peculiar person, both in mind and body. However, he procured from the gentleman who was in regular attendance on the family, some particulars of interest. He told him that on a former occasion he attended the same individual for the same hernia, and at the right side; and that he then made a careful examination with regard to the cleft between the two labia, which he found to end in a cul-de-sac. At the same time he ascertained that urination took place through the orifice of the urethra in the penis. There was an important difference between this case and the one described by Dr. Banon. In Dr. Banon's case the female characters appeared to predominate; in his (Dr. P.'s) case, beyond a doubt, the male organs were more decidedly characteristic. In the one case, the education of the individual was that of a male, though the predominant sex was that of a female. In the other, the education of the individual was that of a female, though the predominant sex was that of a male.

Dr. BEATTY was of opinion that the case just described by Dr. Power was not so manifestly one of fusion of sex as to be entitled to the character of true hermaphroditism, like that brought forward by Dr. Banon; for he did not think that Dr. Power had adduced any evidence to establish the existence of any of the female organs in that case.

Dr. POWER—None whatever, except that the vagina terminated in a cul-de-sac.

Dr. BEATTY thought the person must be regarded as a male, and the case as one of the commonest form of spurious hermaphroditism with which they were acquainted, consisting of an imperfect penis, with a urethra terminating underneath, and constituting hypospadias; a split scrotum and a cul-de-sac, which did not lead to any female organs internally, but was simply a cul-de-sac, separating the two portions of the cleft scrotum. It might be in the recollection of many of the members of the Surgical Society that, several years ago, an individual was exhibited in that room as a hermaphrodite. This person was a Pole, who earned his livelihood sometimes as a female prostitute, passing himself as a female, and wearing female attire in the streets; and sometimes exhibiting himself to medical men for money. On the occasion to which he referred, a sum of £3 or £4 was raised by small subscriptions amongst the members of the profession, and having received that amount he consented to exhibit himself before them. A cast of the individual, which was taken and preserved in the museum, was then lying on the table, where members might have an opportunity of inspecting it. This person was, to all intents and purposes, a male. The scrotum was split; on either side of it there was a testicle, and above an imperfect penis, and a urethra opening underneath, nearly in the position in which the female urethra would open, if it were a female; and in this way contributing to keep up an appearance of double sex. But the individual alluded to by Dr. Power had certainly no right to be considered a female at any time of his existence: he should have been the eldest son of the family (laughter).

Dr. POWER's reason for referring to the case at all was, because the habits and feelings of the individual were so decidedly feminine towards the latter period of her life—a fact which contrasted so strongly with the predilections manifested at an earlier period of existence. Added to that fact, the patient never shaved, never had a beard, and presented in the countenance all the characteristics of the female.

Dr. BANON observed that the history of the case given by Dr. Power, induced him to take the same view as expressed by Dr. Beatty—viz., that it was undoubtedly one of hypospadias malformation in a male. It was quite true, that from education and other causes, a marked modification of sexual peculiarities will often take place. It was well known that disease, such as scirrhus of the ovaries of the female, will not unfrequently cause the individual to lose much of the characteristics of her own sex, and take on those, to a certain extent, of the male; such as a general masculine appearance of the body, the growth of the beard, &c. These peculiarities, sometimes existing from early life, and in other instances commencing

simultaneously with disease of the ovaries after puberty. To such individuals the ancient Romans gave the name of "Virago." In some of the lower animals, particularly in the class "Aves," the same phenomena are observed to exist in a more marked manner. After the hen pheasant has ceased to lay eggs, or to be a reproductive animal, the plumage of the bird will often lose the characters of the female and assume those of the male; and in some instances they have been known even to attempt coition with other hens of their own species. It is not unlikely that in the case mentioned by Dr. Power, the male character of the individual, so well marked in early life, became as he advanced in years much modified by the effects of education and the enforced habits of a female, and perhaps by an imperfect condition of the testes, which has been sometimes observed in hypospadiac males. In the case given by Otto, an hypospadiac male had lived in a state of wedlock with three different men; but at the age of 35, an action of divorce was brought against her by her third husband, accusing her of being affected with some disease of the sexual parts which rendered the connubial act on his part extremely difficult and painful. In this case imperfect testes were found in the cleft scrotum. Cases of similar interest are given by Julien and Soules, and several others, many of which are quoted by Professor Simpson in his admirable article on Hermaphroditism in the second volume of Todd's "Cyclopædia of Anatomy and Physiology." The case given by Dr. Power shows the great importance of our being able to discriminate this form of "spurious hermaphroditism;" as, had the individual married as a female, it would have led to an unnatural connexion between two individuals of the same sex. On the other hand, cases of enlarged growth of the clitoris in the female are sometimes accompanied with so many of the secondary characters of the male, as to give rise to considerable difficulty in determining the sex, as happened in the celebrated case of Marie Madeline Lefôrt, given by Beclard. The presence of menstruation in such cases will be a valuable but not a certain guide.

Mr. TUFNELL did not recollect what Dr. Banon stated was the character of the voice in the individual whose very remarkable case he had produced before the Society this evening.

Dr. BANON believed he had stated that the voice of Andrew R— was essentially that of the male. His companions stated that he was exceedingly active, and able to undergo much fatigue; and he guarded his secret with the greatest care, it being known only to his nearest relatives. He might state before sitting down that, from the narrowness of the vagina, it was next to being impossible that this individual could have connexion with a male, and the imperforate state of the penis would render effectual connexion with a female quite impossible.

Dr. POWER agreed with Dr. Banon that education had a considerable modifying effect on the tastes and habits of such individuals, putting sex out of the question altogether.

#### PRESIDENT'S ADDRESS.

GENTLEMEN,—As the present session of the Surgical Society is about to terminate its scientific labours on this evening, I cannot allow myself to perform the official duty which necessarily devolves on me as your chairman, that of adjourning the future meetings of its intellectual reunions to another session, without offering to the Society my sincere congratulations on the unexampled, though not unexpected success which has attended its praiseworthy exertions, uniting, as I am happy to say it has done, in a bond of friendly union and professional kindness, persons distinguished for scientific acquirements, mental endowments, and medical experience, constituting thereby a well-arranged combination of talent and genius, so preëminently necessary for the attainment of that common object so deeply interesting to us all—the improvement of science, and the advancement of medical literature in this country, abolishing at the same time, from all its sessional meetings, those petty jealousies and controversial feelings which have so frequently been found, by their blighting influ-

ence, to have disturbed the pure course of scientific information in its onward progress.

I can assure you, that it is with no small degree of satisfaction that I contemplate the many advantages that we, as medical practitioners, are likely to derive from the gradual, but certain strides which this Society is now making, developing, in each succeeding session, as it steadily advances, a fresh store of professional information and native talent; adding thereby to the existing fund of medical knowledge, subjects of the most erudite and practical character, creditable not only to this Society, from their originality and professional importance, but also beneficial to mankind in general, by contributing to the advancement of medical knowledge—to that scientific eminence which is the main object of this enlightened body to organize and stimulate.

It is not my intention, in addressing you on this occasion, to occupy your time by entering into a lengthened or unnecessary detail of the different proceedings of the past session, as I feel that it would only be a tedious repetition of those statements and observations which have been already so ably and eloquently set forth on former occasions by those distinguished individuals who preceded me in this chair. There are, however, some few matters connected with that period, which may perhaps claim our notice; but I shall merely refer to them for the purpose of directing attention to the working of this Society, and to the able and scientific manner in which it has, by your assistance, carried out the noble intentions of its original founders, reflecting thereby much honour and dignity on this College, under whose auspices it has been established, and within whose walls it holds its usual scientific reunions, and developing, at all its assemblies, the same praiseworthy feelings of professional liberality for which this College has always been distinguished, where the true object of attainment was the advancement of science, or the promotion of professional literature.

I feel that it is unnecessary for me now, at this advanced period of the evening, to expatiate, at any length, on the beneficial effects which this Society is capable of exerting, in the promotion of science, and the advancement of medical knowledge, by holding out, as it does, a favourable opportunity to persons of scientific pursuits, professional observation, or mechanical taste, of associating with others of similar acquirements, whilst, at the same time, from the marked encouragement it affords to free discussion and scientific investigation, a favourable opportunity is also given for communicating their peculiar opinions in a friendly and agreeable manner, thereby establishing a familiar mode of arriving at satisfactory conclusions, as to the intrinsic value or scientific merit of each particular subject. An opportunity is also afforded here, to the industrious and working members of this Society, through the instrumentality of their well-arranged scientific contributions and professional essays, of not only distinguishing themselves amongst their fellow practitioners, but also of exalting the character, and establishing the importance of the medical profession in popular estimation, and thus creating, by their distinguished example, a taste amongst their professional brethren, for cultivating those collateral branches of the arts and sciences which are now so intimately connected with our professional pursuits, and which consequently tend, by their scientific importance, to assist, most materially, in advancing the true interests of the medical profession, and encouraging, at the same time, by the friendly association which generally takes place at its usual sessional reunions, a kindly intercourse and good feeling amongst its numerous members, proving in the most satisfactory manner, that free discussion and scientific competition can be carried on here amongst medical practitioners, without exciting either envy, animosity, or unkind opposition, the true bane to the advancement of professional knowledge.

I find, on consulting the records of the Surgical Society, as well as from the opportunities which have been afforded me in this chair, that the scientific intentions of the original founders of this Society have been most faithfully

carried out during the interesting proceedings of the past session, through the able exertions and indomitable perseverance of its indefatigable secretaries—gentlemen to whose eminent and laborious services this Society owes much of its present success, and to whom we must all feel deeply grateful, when we consider the devotion and care they so generously exhibited, in promoting the praiseworthy exertions of the different distinguished members of this body, who, with so much philanthropy and disinterestedness, contributed to carry out the true intentions of this Society, by the able and ingenious essays which they brought before the different meetings, written with so much clearness, accuracy, and conciseness, full of originality, and illustrating, at the same time, the different subjects with a vast prodigality of facts, and well chosen, practical applications, which rendered the subject matter attractive, instructive, and professionally interesting; whilst on the other hand, those essays which were written on subjects apparently of less interest in themselves, although of vast professional importance to the medical practitioner, were rendered attractive and agreeable, from the peculiar clearness of the description, whilst the more important points of interest were generally illustrated by the relation of interesting cases, which, whilst they relieved the painful efforts of attention, served, at the same time, to impress the subject on the mind, in so agreeable a manner, that it made an impression that could not easily be effaced, thus convincingly establishing the scientific importance, professional merit, and practical benefit of those valuable and instructive papers, pregnant, as they were, with originality and professional information, which rendered them the prolific source of medical discussion and elaborate debate, during the different interesting scientific meetings of the past session.

I feel from the warm interest I take in the welfare of this Society, that I may have been induced to have entered more minutely into some of its proceedings, than I otherwise intended to have done. I consequently fear that I may have thus inadvertently left myself open to the well-deserved imputation of having been more prolix on this occasion, than was either necessary for the benefit of my cause, or agreeable to the wearied patience of my kind auditory. I shall not, however, now trespass longer on your kindness by entering further into the merits of the scientific exertions of the different members of this enlightened body who have so devotedly laboured in the cause of science, with such splendid results, creditable not only to this Society, but also beneficial to the best interests of the medical profession.

Judging, therefore, from our experience of the past, I feel we may be induced to look forward with the most favourable and auspicious anticipations to the future, and fondly hope that medical science, whilst under the fostering care of such distinguished patronage as this Society affords, cannot but flourish, shedding lustre on this College, and benefit on mankind.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

### AN ANALYSIS OF ONE HUNDRED CASES OF CANCEROUS DISEASE OF THE UTERUS.

By ROBERT LEE, M.D., F.R.S., &c.

THE conclusions to which the author arrived from this analysis were:—1st. That cancer may commence in any part of the mucous, muscular, or peritoneal coats of the uterus; but most frequently in the os and cervix. 2ndly. That the earliest symptoms of the disease, in a large proportion of cases, were discharges of sanguineous, serous, or white-coloured fluid from the vagina, with sense of uneasiness or pain more or less acute within and around the pelvis. 3rdly. That cancerous disease of the uterus presented itself most frequently in the form of induration and ulceration of the os and cervix uteri and vagina, or ulceration without induration, or in the form of fungoid tumours, usually called cauliflower excrescences, growing from one of the lips or the whole os uteri, being often associated with encephaloid or colloid masses and true scirrhus of the

remaining portions of the uterus and contiguous viscera. 4thly. That in no case could cancerous disease of the uterus be referred to inflammation; and that its fatal progress was never arrested by cauterizing the morbid structures through the speculum, nor by any other method of treatment.

### AN ACCOUNT OF A CASE OF PULSATING TUMOUR, IN WHICH THE URINE CONTAINED CANCER CELLS.

By C. H. MOORE, Surgeon to the Middlesex Hospital.

A greengrocer, aged 53, was admitted into the Middlesex Hospital, with a large pulsating tumour in the left groin, and congestion and great œdema of the left lower extremity as well as of the buttock and lower part of the abdomen. The tumour lay precisely in the situation of external iliac aneurism, was smooth and rather firm in most of its surface, but was in part lobulated and soft. As it was so large as to raise the structures above, its beat was visible. The pulsation raised the hand laid on the tumour, expanded it slightly when the tumour was grasped, and was felt more strongly when the femoral artery was compressed. It was stronger at the soft prominences than at other parts of the surface; and the external iliac artery was felt running over its anterior part. The tumour presented a distinct bruit. The first symptom of the disease could be dated at three months before the patient was seen; the pain was severe and of a pulsatile character. The tumour was at first considered to be a mass of enlarged iliac glands; but as in the eight days in which it was observed it increased in size, and beat more vigorously, and thrust out a new lobe from its surface, at the same time that the general circulation became tranquil, it was then presumed to be an aneurism in which part of the blood had coagulated. As the tumour thus rapidly increased, and the pain became very severe, the common iliac artery was tied. The operation performed was similar to that described by Sir Philip Crampton, the external incision reaching from the extremity of the 12th rib nearly to the anterior superior spine of the ilium. The patient survived the operation forty-three hours, and died with peritonitis, failure of the circulation in the limb, and most marked disorganization of the blood. The tumour was the largest of several masses of enlarged glands affected with encephaloid cancer. It lay against the ilium, and was enclosed in thick fascia, which had given way at the soft prominences felt during life. It was somewhat tightly girt in almost a circle of arteries, the external iliac being stretched and flattened along its upper surface and beneath the fascia, the internal iliac lying in contact with its posterior part, and the obturator artery beneath it completed the circle, except where the tumour and pubes intervened between it and the external iliac trunk. Moreover, the large branches of the internal iliac passed through the tumour. There were small secondary cancerous depositions in the kidneys, and an encephaloid growth sprang from the back of the prostate gland (which was otherwise healthy), and extended upwards between the bladder and rectum. This appeared to be the primary growth. Some urine, pressed out through the urethra after death, was examined by the microscope, and was found copiously pervaded with cancer cells. That which had been observed during life, being clear, was not examined microscopically. The author concluded his paper by some remarks on the distinction of pulsating tumours and aneurisms, and on the importance of the last-mentioned fact as a possible means of diagnosis in another doubtful case.

### REMARKS ON THE PATHOLOGY OF HYDROPHOBIA, WITH AN ACCOUNT OF A CASE OF THAT DISEASE.

By GEORGE ROBINSON, M.D., of Newcastle-on-Tyne.

The author observed that the obscurity of the pathology of this disease gave importance to any additional facts that bore on its solution; and he thought that a case which had recently occurred in his practice, presenting the usual characteristics of this affection, suggested certain conclusions. The author entered at full into the history of the case, which presented nothing novel, whether of symptoms or of the progress of the disorder. A post-

mortem examination developed no condition not previously noted in similar cases. There was the usual congestion of the pulmonary mucous membrane, and the tubes filled with a tenacious mucus; the several parts of the encephalon were vascular and injected; lymph was observed at the base of the brain, on the cerebellum and medulla oblongata; and many red points were observed on section of the substance of the cerebral mass. The conclusions to which these facts led him were:—1stly. That the disease, from the moment of its manifestation, essentially consisted in a morbid irritability of certain parts of the nervous system, and particularly of the medulla oblongata and base of the brain. 2ndly. That this morbid irritability and inordinate excitement of that part of the brain most intimately connected with the nerves of deglutition and respiration, in accordance with the known laws of the pathology of the nervous system, produced spasmodic action of the muscles of the glottis and pharynx, and an unnatural sensibility of, and excessive secretion from, the mucous membrane of the pharynx and fauces. 3rdly. That the exhaustion consequent on the spasms thus excited, and the asphyxia ultimately induced by the introduction into the air-passages during inspiration of the viscid mucus thus copiously secreted, were the immediate causes of death. In regard to the treatment of this disease, the author thought that, from the general symptoms, as well as from the most simple views of its pathology, the propriety of tracheotomy in the first stage could not be questioned. He considered that this operation would prevent the accumulation of viscid mucus in the trachea; he was disposed to follow up this act by the use of terebinthinate, and subsequently of anodyne and antispasmodic enemata, and when practicable a general vapour-bath.

An abstract of a case of biliary fistula by the same author was also read. It occurred in a woman, the wife of a pitman, aged 64. Severe gastric and dyspeptic symptoms, followed by jaundice, ushered in the appearance of a tumour in the epigastric region. This tumour gradually softened, fluctuated, and pointed; after a time it was deemed advisable to relieve her by opening this prominent indication of abscess, and two quarts of a bright yellow, very offensive liquid, a mixture of bile and pus, escaped from the wound. The symptoms of the patient underwent immediate improvement; no constitutional disturbance followed; a good diet, with beer and cinchona, rapidly improved the general health; the discharge quickly decreased, and the opening made by the lancet simultaneously contracted. Three months afterwards, a yellow discharge continued from the fistulous opening, and which constituted her chief complaint, as her general health permitted her to engage in the least onerous of her domestic duties. By means of a suitable glass retained over the opening, a quantity of this yellow fluid was collected, and submitted to Dr. Bence Jones for examination, who pronounced it to be pure bile. The amount of the discharge varied under different circumstances and at different periods. The quantity was estimated at eight fluid ounces daily. The flow was more rapid after meals, also during the erect position; it was augmented also by straining or coughing. The alvine dejections had not recovered their natural colour, being light clay-coloured, many months since the opening was established. Of late the patient had become much more reduced. At the last visit the discharge of bile was as copious as in the early date of this fistulous opening. Rapid emaciation was proceeding, which the author thought partly due to the withdrawal of her beer and adequate nourishment, but nevertheless aided by the profuseness of the biliary discharge. —*Lancet*.

**FRACTURE OF THE RIBS.**—The two points of mechanical treatment in fracture of the ribs is, first, rest; and second, bandaging the chest, by fixing straps of adhesive plaster, circularly from the spine to a little beyond the sternum, on the injured side only, leaving the other free, as well as the abdomen on both sides. (Mr. J. Hilton.)

## ON EDIBLE EARTHS.

By EHRENBERG.

VARIOUS kinds of edible earth were known in China in very ancient times, and it may be presumed, that many of them are mixed or pure tripolitan fresh water bioliths—i.e. species of earths or stones, the elements of which consist chiefly of remnants of microscopic living beings. In the year 1839, Biot read before the Academy of Sciences in Paris a treatise, containing everything that was then known on this subject, to which his son, the oriental linguist, Biot, furnished translations from Chinese and Japanese works. From Schott in Berlin, Professor Ehrenberg obtained in addition the following information taken from Chinese sources. The first mention of edible earth dates from the year 744 after Christ, and is contained in the Chinese work Pen-tsao-kang-mu, where it is called Schi-mián, Stonebread, or Mi-án-schi, Breadstone; the article in the Japanese "Encyclopædia," which Biot has translated, is taken from this work. The Pen-tsao says, according to Schott, that stones contain several substances which are edible, especially a yellow meal and a fatty liquid, which is contained in the white Yü (a stone), and is, therefore, called the fat, marrow, or mucilage of the white Yü. An earthy substance, prolonging life, and called Schi-naó, is found in the very smooth stone Hoa-shi, which is supposed to be Steatite, and may, perhaps, be decomposed Steatite. The Schi-mián is only used as a substitute for bread in times of scarcity, when it is miraculously found in different localities, as is believed. The imperial annals of the Chinese have always religiously noticed its appearance, but have never given any description of the substance. The Pen-tsao quotes, under the emperor Huan-Tsung of the great dynasty Táng, in the third year Tíán-pao (744 after Christ) a spring in Wujín (now Liang-tschen-fu, in the province Kan-su), which ejected stones, that could be prepared into bread, and were gathered and consumed by the poor. (Schott.)

Under the emperor Hian-Tsung, of the same dynasty, in the ninth year of the period Yüen-ho (809 after Christ), the stones became soft and turned into bread. (Biot.)

Under the emperor Tschin-Tsung, of the dynasty Sung, in the fifth year of the period Ta-tschoong-Tsiang-fu (1012 after Christ) in the fourth month, there was a famine in Tsy-tschen (now Ki-tschen in Ping-yang-fu, in the province Schan-si), when the mountains of Hiang-ning, a district of the third rank in the same part, produced a mineral fat (Stonefat) resembling a dough, of which cakes could be made. (Schott.)

Under Jin-Tsung, in the seventh year of the period Kia-yeu (1062) stone meal was found. (Biot.)

Under Tschí-Tsung, in the third year of the period Yuen-fong (1080) the stones turned into meal. All these kinds of stone-meal were collected and consumed by the poor. (Biot.)

Very recently, in the years 1831 to 1834, similar kinds of earth have been found in China, and were used as food during the great famine, as has been reported by the Chinese missionary, Mathieu-Ly, who resides in the province Kiany-si. In the year 1834 he writes:—"Many of our Christians will surely die this year from starvation. The Almighty alone can aid them in such great distress. All harvests have been destroyed by the floods. For three years a large number of persons have lived upon the bark of an indigenous tree; others have eaten a light white earth which has been discovered in a mountain. It can only be obtained for silver, and not every one can, therefore, procure it. The people have first sold their wives, then their children, then their furniture, at last they have pulled down their houses and sold the wood. Many of them were, four years ago, wealthy men." The missionary Rameaux, also reported in 1834, from the province Hu-kuang, that many Chinese Christians have sent for him to administer to them the last sacrament, and foreseeing the hour when they were to die from starvation, actually died at that very time. The very dense population and industry which necessarily takes possession of everything.

are, in cases of earthquakes and deluges, the cause of these circumstances in China.

The districts where stone-bread has been found are the northern province of Schan-si, the east provinces of Schantung and Kiang-nan, on the mouth of the Yellow river (Huang-hu), the provinces Hu-kuang and Kiang-si, in the valley of the Blue river (Yantse-kiang). It is very desirable to know the masses, localities, extent of occurrence of these earths, as well as their geognostic character. The analysis of the two kinds, which the author has obtained, renders it very probable that all similar substances belong to antediluvian deposits, some of which are very probably tripolitan, fresh water bioliths of infusoria, while others appear to be clay mixtures or real clays. (Letten.)

*A White Edible Earth of 1834, from China.*—The author obtained, in the year 1841, by Humboldt, from Paris, a sample of the edible white earth, sent to Paris by the French missionary in China. One of the two pieces measured two inches in diameter, the other one inch. It has a white colour, similar to chalk, but is as light as *Kieselguhr* or Meerschaum, is somewhat fatty to the touch, not soiling the fingers, but very brittle. The pieces having been broken in those directions which were indicated by a previous crack, some of the internal surfaces had a rusty colour, but only superficially. Acids caused no effervescence. According to the analysis, this earth is merely silicate of alumina, the peculiar lightness of which is striking. If heated, it assumes a gray colour. In fifteen samples no organic mixture could be discovered by microscopic examination, which latter shows also no similarity between this substance and Meerschaum; there is also an entire absence of magnesia. This earth has much resemblance to lithomarge-like Kaolin, but its lightness and the different form of the microscopic parts, admit no identity between them. Irregular, mostly globular bodies of various sizes, with soft obtuse outlines, compose the whole mass. Perhaps it is a deposit of a precipitate from hot siliceous waters.

From the blackish mould left in the impressions of the smoothly scraped natural surface, it is obvious that the fossil has not been taken out from the midst of rocks, but was dug out from a black mould. Analyses have shown eighteen different microscopic forms, which are enumerated in the 294th analyses of the microgeological researches of the author.

*B. Yellow Edible Earth from China.*—In the year 1847 the author obtained from one of the great geological collections in London a small sample of this earth, which from a gray passes almost into a sulphur-yellow. It resembles a very fine clay, does not soil the fingers, but is brittle, and shapeable when moistened. Acids produce no effervescence, and when heated it becomes first black, then somewhat reddish. Its microscopic elements are a rather coarse, double refracting, mostly quartz sand, surrounded by a somewhat finer mould. Intermixed are isolated, small green and white crystals, mica, and Phytolitharia, with now and then traces of Polygastric shells and silicious casts of stone kernels of Polythalamia. In ten analytical examinations were found fourteen forms: one Polygaster, nine Phytolitharia, one Polythalamium, and three crystals. The substance is therefore, according to this, a loamy or clayey substance. All the Phytolitharia contained in it are in a corroded porous state, just as they occur in antediluvian tertiary layers. The presence of Polythalamia, and in particular of *Textilaria globulosa* in a stratum, very likely of the interior continent, indicates chalk formations in the vicinity of the place, or at least in the aquatic district of the river. This appears to prove that the clay similar to the edible Tanah ambo in Java, which it very much resembles, is a tertiary fresh-water formation in the modern sense of geognosy, incumbent on chalk, or mixed with fragments of chalk. The forms occurring in it are:—

1. Polygastric: *Trachelomonas levis*.

2. Phytolitharia: *Lithodontium Bursa*, *L. nasutum*, *L. rostratum*, *Lithosphæridium irregulare*, *Lythostylium clavatum*, *L. leve*, *L. quadratum*, *L. rude*, *L. Trabecula*.

3. Polythalamia: *Textilaria globulosa*.

4. Inorganic forms: green crystalline prisms, white crystalline prisms, plates of mica.

The sum of the discovered species is eleven organic forms and three inorganic ones; among which are ten fresh-water formations and one marine formation, *Textilaria*.—*Pharm. Central Blatt* and *Phar. Jour.*

## ON THE IODIDE OF POTASSIUM IN SYPHILIS.

THE following remarks upon this subject are made by the Reviewer in the *British and Foreign Medico-Chirurgical Review*:—Dr. Williams was the real discoverer of this influence, perhaps the greatest therapeutical discovery of the age, after that of the anæsthetic effects of ether and chloroform. His paper was read at the College of Physicians in 1834, five years before Ricord began his experiments; and so far from giving it indiscriminately in all cases, he took the greatest pains to investigate its real powers, and pointed out where it was efficacious and where useless; not with hesitation, but with all the open candour of his nature. In his "Elements of Medicine," while showing the marvellous certainty of its action in rupia and the hard periosteal node, he showed that its power was much less in roseola, purpura, and ecthyma, but still it was better than mercury; while in lichen, lepra, psoriasis, and iritis, he proved, with equal clearness, that mercury, either locally or generally, had far more beneficial influence than the iodide. He pointed out the curious fact, that while the action of the iodide on hard periosteal node was as certain and evident as that of quinine in ague, when once suppuration had commenced, sarsaparilla was the remedy, the iodide being useless. In soft node and prurigo, he showed the true power of sarsaparilla; and in syphilitic angina and rupia, the invariably good effects of combining local mercurial applications with the internal administration of the iodide. We witnessed many of his experiments, and for the last twelve years have been guided by his results, without having ever had cause to regret it; and after tolerably extensive opportunities of treating secondary symptoms, the only modification we have learnt to make in his practice, is the occasional use of the proto-iodide of mercury in lichen and in some of the affections of ligaments and synovial membranes. We almost always give the dose recommended by Dr. Williams, eight grains three times a day in water or camphor mixture; and when using the proto-iodide of mercury, begin with one grain daily in divided doses, increasing gradually to three or four grains in the day, made into pills with liquorice, or with catechu, if it acts on the bowels. Opium appears to destroy its power altogether. We never saw any good done by giving a mercurial course before the iodide, as many recommend, but often much harm. On this point, and on the relative powers of iodide of potassium and mercury in syphilis, we would refer to a work in which the investigation has been made in the true spirit of science by Dr. Hassing of Copenhagen.

## RECOVERY FROM POISONING BY STRYCHNIA.

By J. COOPER FORSTER, M.B. Lond., F.R.C.S.

Very little apology is needed, I think, for troubling you with the following interesting case. I am indebted to Mr. W. C. Hills, house-surgeon to the Surrey Dispensary, who first saw the patient, for the main facts:—S. S., aged 52, a dissolute hypochondriac, with a constitution and intellect considerably damaged, was under my care with indolent ulcers on both legs; and on account of dyspeptic symptoms, from which he also suffered, I ordered him one-twelfth of a grain of strychnia, to be taken three times a day. For convenience and accuracy in dispensing, an acid solution of strychnia is kept at the Surrey Dispensary, in the proportion of one grain to an ounce of water, and this patient had an ounce and a half of that solution given him, a teaspoonful of which contained the dose required. From inattention to both verbal and printed instructions, on his return home he took rather more than an ounce of the medicine, which he had not swallowed above ten minutes when he became violently convulsed. On discovering his

mistake, he immediately took copious draughts of cold water ; but the convulsions increasing in severity, his friends became alarmed, and he was driven in a cab to an hospital, when, being refused admittance, he was again brought to the dispensary. An hour and a half had now elapsed since the poison was taken, during the whole of which time his attendant stated he had been violently convulsed. When Mr. Hills first saw him, he had trismus, with the upper and lower extremities completely rigid, and paroxysms of opisthotonos and emprosthotonos occurring alternately. A paroxysm now took place every six minutes, each one lasting about two minutes, and during the emprosthotonic condition he uttered a violent shriek. He had half a drachm of sulphate of zinc given immediately, and was sent home, and placed in a warm bed. I saw the patient with Mr. Hills about four hours after the poison had been taken, and found that he had been slightly emetized by the zinc, and had also been most violently purged. The tetanic rigidity still continued; the paroxysms were, however, less frequent; the patient could only lie on his back, and the slightest exertion brought on the convulsive attacks. The bladder also seemed to participate in the general contraction of the voluntary muscles, and expelled small quantities of urine, as fast apparently as it flowed into that viscus; the pupils were natural; the pulse small and irritable; and the whole frame was evidently much exhausted and enfeebled. He was now ordered frictions over the spine by means of soap liniment, which afforded him great relief, and half a drachm of the compound spirit of sulphuric ether in camphor mixture to be taken internally every four hours. During the night he continued to have involuntary twitchings of the limbs, which lasted also through the following day; on the second night they became more severe, but were only of a few hours' duration, and then entirely left him. He has since returned to his work in his usual health.

I find Dr. Taylor states, in his valuable work on poisons, that he has been informed of a case in which a grain of strychnia had been taken, vomiting had supervened, and the patient had recovered; but he does not authenticate it, and moreover states that half a grain proved fatal to Dr. Warner in fourteen minutes. From this a doubt naturally arises in one's mind, whether the strychnia in the present instance was of good quality, as a dose far beyond the average was swallowed, and in solution, which so much favours absorption; and yet the patient recovered. The extreme urgency of the symptoms, however, I think, sufficiently proves the genuineness of the drug; and I can therefore only attribute the favourable result to the large quantity of cold water swallowed, which appears to have acted as a powerful aperient, carrying the poison rapidly along the alimentary canal. With regard to the treatment adopted at the dispensary, it appeared the only course left to be pursued, as no antidote is known; and the result, I think, proves the value of the zinc administered, and justifies the supposition that this drug acted as a stimulus to the distended intestines to get rid of their contents, as almost immediately after the emetic was swallowed violent purging took place, with only very slight emesis.—*Lancet*.

**IODINE INJECTIONS IN ASCITES.**—Notices have from time to time appeared in the French journals upon the treatment of ascites by iodine injections, some of which we have transferred to our pages. The chief advocate of the practice is M. Boinet, who has published a long memoir on the subject (*Gazette Médicale*), the completion of which has recently appeared. In this concluding paper a *résumé* of his experience is given, from which it appears that he has performed the operation in thirteen cases, eleven of which were successful. No injurious consequences followed the injection in any instance, if we may believe the reports; and one injection was generally sufficient. The deductions with which the author concludes his memoir are these:—1. That various fluids may be injected into the peritoneum without danger, and with manifest benefit, in the treatment of ascites. 2. That, of these various fluids, the tincture of iodine is indisputably the best, of which an abstract is given in the *Archives Générales*.

## CASE OF EXCISION OF KNEE-JOINT.

By G. M. JONES, Esq., Surgeon to the Jersey Hospital.

SARAH HANSFORD, aged 25, was admitted into the Jersey Hospital on the 1st of January, 1851, on account of a disease in the knee. When nine years old she had an inflammation in the knee, arising, it is supposed, from exposure to cold. Since then it has scarcely ever been free from pain, and has always been considerably larger than the right one. The catamenia came on at 16, and has been regular since. In April, 1848, she was admitted into the Reading Hospital, and the report of her case from the books of that charity is as follows:—"Disease of left knee, involving synovial membrane, probably cartilage, and also ligamentous and cellular tissue; knee much enlarged; the slightest movement gives pain."

**Present appearance.**—The affected joint is very much enlarged, more particularly on the inner part; it is exquisitely tender on pressure; the swelling throughout is elastic and glossy, and the superficial veins very much enlarged. The knee presents, in an aggravated form, the appearance described by Mr. May. For the last few months she has suffered more in it than she had done before; she sleeps but little in consequence of frequent lancing pain, and this sleep is unrefreshing; she has scarcely any appetite; pulse ranges from 100 to 105; has lately perspired freely towards morning. States that she has become much thinner.

As there could not exist a doubt respecting the nature of the case, or that the disease was progressing rapidly, it was decided, in consultation, that, in consequence of the absence of any very formidable symptom, this was possibly a case in which excision of the joint might prove successful; and as the patient was willing to submit to any operation or treatment, save the removal of the limb, she cheerfully acceded to a proposal which her repugnance to losing her leg had in a great measure suggested.

On the 19th, one week after the cessation of the catamenia, the operation was performed (the patient being under the influence of chloroform) in presence of several of my medical friends, some of whom kindly assisted me on the occasion. The patient was so placed on the table as to allow the leg and the greater portion of the thigh to hang over it. As a very minute examination, together with the appearance of the knee, indicated that extreme disease existed, I made my lateral incisions midway below and above each side of the joint, about five inches in length, cutting at once down to the bone. These were united by a transverse one, carried across immediately over the centre of the patella. The flaps were then dissected backwards and forwards, and the patella, which was soft and spongy, removed; the surrounding soft parts of the femur were then cautiously detached as high up as disease appeared to exist, and the crucial and lateral ligaments were divided; this allowed the assistant who had charge of the leg at once to bend it backwards, while the other raised the thigh from below upwards. By this means considerable facility was afforded for clearing the posterior part of the femur of its different attachments. The joint thus exposed discovered the cartilaginous surfaces of both femur and tibia destroyed by ulceration, and a considerable portion of the osseous surfaces in a state of caries. There was pus external to the joint as well as in the joint itself. The removal of the diseased part of the femur was accomplished with the common amputating saw; a large portion of the head of the tibia was also taken off with the same instrument. The fibula was found sound; neither spatula nor retractor was used. The hæmorrhage was very trifling; no vessel required a ligature. The length of bone removed was four inches. The edges of the wound were now brought together with sutures and a few adhesive straps, the bones placed in juxta-position, cold-water dressings applied, and the limb secured in a modern apparatus (in some respects similar to Sir Astley Cooper's fracture-box). The whole of the operation occupied twenty minutes.

The patient returned to consciousness very soon after being placed in bed. The pulse was extremely feeble and correspondingly quick, extremities cold, and features somewhat attenuated. She evinced much surprise on finding that the operation was over. Warm flannel was applied to the hands and feet, and brandy and water given. The pain being excessive two hours after the operation, 50 drops of tinct. opii, in camphor julep were taken. She has experienced much nausea, and has vomited twice, evidently the effects of chloroform, as similar symptoms occurred three days before, when its effects were tested on her. Nine p.m.: Still suffers much pain, and is inclined to be restless, but not

to the same degree as before the anodyne. Has taken nearly a pint of strong beef-tea, with pepper in it. The anodyne (same quantity) to be repeated. Midnight: Has slept by snatches since the last visit; pulse 115, and weak; much less nausea. Beef-tea to be continued, and port wine and water to be taken occasionally. 20th, Mane: has slept about two hours, and altogether feels more comfortable. No heat whatever of the limb. Pulse 110, very feeble; tongue moist, but rather coated. No return of vomiting or nausea. A glass of port wine every three hours, each glass to be preceded by one ounce of quinine mixture equal to two grains per dose. Beef-tea *ad libitum*. Vespere: Pulse 106; feels comfortable; but little oozing from the wounds; some tenderness, but only on pressure; tongue moist. The affected leg and foot the same temperature as the other. The kidneys act freely.

Feb. 28th: To have continued a daily account of this case from the last report to the present time would have been a tedious recapitulation of almost the same appearances and symptoms, together with the same treatment as have already been noticed. For the first eleven days after the operation, there was not a single unfavourable symptom, not one to cause the least uneasiness for the patient's life; and since that time she has progressed satisfactorily—perfectly so, as far as her health is concerned, for it is now considerably better than it had been for many months, and favourably also as regards the appearance of the knee; the tumefaction naturally resulting from an operation of this nature has considerably subsided; there exists scarcely any cedema of the leg; and although the discharge is considerable, and evidently from sinuses both above and below the parts once forming the knee-joint, still it is of a healthy character. Pressure on the parts can now be borne with much less pain than formerly. The appetite has also improved. The bowels are constipated (as they have generally been); care, however, has been taken that they should be relieved every second or third day. The renal secretion continues natural. The same dressings to be continued, and also the same nutritious diet. Quinine and port wine as usual.

March 20th: Felt feverish during the night, and experienced several rigors. Complaints of throbbing pains rather better than midway down the thigh. Two openings in the fore part of the knee have been closed for the last few days, and the pain complained of evidently arises from pent-up discharge; in other respects everything is going on favourably; pulse is rather accelerated—90 (till now it has ranged from 76 to 84); some thirst; tongue clean, countenance cheerful; bowels as usual. Porter and quinine to be omitted; saline aperient to be taken immediately, and the hot-water dressing with oil-silk, &c., to be applied over the fore part of the thigh and transverse incision of the knee. 21st: Feels comfortable this morning, and slept tolerably well the latter part of the night. The aperient acted twice. Pulse 80. A considerable quantity of healthy pus has made its exit through the former openings. Tenderness of the thigh has almost altogether subsided. Has for the last week complained occasionally of pain in the back, arising most probably from the catamenia not having appeared. Hot-water dressing to be continued. Wine and porter as before. The quinine to be omitted, and 3j of mist ferri. com. to be taken twice a day. 31st: Health continues to improve; appetite very good. There is much less discharge from the knee; nights are very good; catamenia has not yet appeared. Diet as usual; medicine also.

April 10th: The catamenia came on yesterday. The appearance of the knee continues favourable: feels weak; pulse is, however, good, and everything connected with the digestive organs healthy. Omit medicine. Food of the most nutritious kind to be continued. 30th: The leg was taken out of the box to-day, and gutta percha splints, moulded to the shape of the knee, applied. The wounds have all healed with the exception of one place about the size of a sixpenny piece, situated at the upper part of the inner lateral incision; from this there still continues a discharge, but by no means considerable. Complete bony union has not taken place, as there exists some degree of flexion and extension; she can, however, without any other assistance than that given by the splints, raise the whole limb, and keep it raised for some time. Her health has wonderfully improved.

May 15th: Has been down into the open air every day since last report, and finds herself stronger than she has been for two or three years past. The small wound has not healed, but looks healthy; with the assistance of a crutch

and a high-heeled shoe she is able to walk very tolerably. 24th: Was able to walk across the room without any assistance, and, notwithstanding my persuasions to the contrary, at the instigation of her husband, she left the hospital. On July 17th she was re-admitted. During her absence she had had many hardships to contend with; the ill-usage of a drinking husband, the sole care of a family, and scanty provisions; which, together with the neglect of dressing the knee, and the being obliged to move about every hour of the day, necessarily produced considerable mischief; so that instead of the small healthy wound which existed when she left the hospital, and which, had she remained there, would, I feel convinced, have disappeared within a month, I had now the mortification of finding several small sores communicating with sinuses, and a considerable discharge flowing from them. Perfect rest was again enjoined, and this, together with nourishing food and malt liquor, gives me every hope that her imprudent step will have no worse result than that of retarding the cure. The knee, at present, is almost entirely healed, and again (with the assistance of a very ingenious frame made by a gunsmith of this place) she is able to walk with a stick; and I confidently expect that ere long she will do so without this adventitious help. She has not a single ailment, and is much stouter than she has ever been before.—*Med. Times and Gazette.*

### ON LIQUID VACCINE LYMPH.

By Mr. CHATTERLEY.

I enclose you two little tubes made of gutta percha, with stoppers of the same material, into which are inserted blades, one of glass, the other of ivory. By collecting the fresh lymph on either of these blades, and replacing it in the tube, it is confined in an air-tight vessel, very light (weighing only from twenty to thirty grains, being about two inches long, and a quarter of an inch internal diameter), quite inflexible, capable of retaining the lymph in a liquid and useful condition for at least three weeks or a month.

I will not here enter into the discussion of the question as to how long lymph may be kept in a liquid state without undergoing decomposition, but will say, that I have used it successfully after having been stored in these tubes for about four weeks. When intended for transmission to great distances, to ensure that they are hermetically sealed, the stopper and mouth of the tube may be warmed in the flame of a taper, and united while hot; they may afterwards be separated by passing a sharp or warm knife a little below the mouth of the tube; in ordinary cases, if the stopper becomes fixed, it may generally be easily removed by grasping it with the corner of a handkerchief, or with a small pair of flat pliers, using in each case a slight rotatory motion. I am about to try some steel points, instead of glass or ivory, so as to render but one instrument necessary.

Mr. Chatterley has obligingly forwarded to us two of the little stoppered tubes such as he has described, and they appear to have been ingeniously designed; but probably he is not aware that, a few years since, vaccine lymph was supplied from the Vaccination Hospital, Battle-bridge, in half-drachm or drachm stoppered bottles, the stopper forming within the bottle a sharp-pointed cone, on which a drop of the lymph was deposited. Two children in the parish of Clerkewell were vaccinated from lymph thus supplied. It was taken from a remarkably fine, healthy child, on the eighth day after vaccination. The two children were of the respective ages of six and two months. The arms of both children became highly inflamed, the wound on the arm of the eldest child sloughed, and the infant died on the fourteenth day after it was vaccinated. The other child survived; but abscesses formed in the axillæ, the elbow, and wrist joints, and other parts of its body. Both children having been so severely affected, and one having died, an inquest was held on the body before Mr. Wakley, and the case was minutely and thoroughly investigated. Mr. Marson, of the Vaccination Hospital, was present at the inquest, and the lymph that remained attached to the point of the cone was submitted to a microscopic examination by Mr. Wilson, who proved, at the inquest, that it had become completely decomposed, and quite unfit for use. It should be stated that the children thus affected by the lymph in question were vaccinated between thirty and forty hours after it had been taken from the arm of the healthy infant. At the conclusion of the inquiry, Mr. Marson stated that the practice of sending out lymph in a liquid state, and in such a manner as to admit of its decom-

position, would be immediately and henceforward discontinued at the Vaccination Hospital.—*Lancet*.

Since the foregoing was in print, we have received a second communication from Mr. Chatterley on the same subject:—

SIR,—Since I wrote to you there has been a discussion at the Epidemiological Society, in which I took a part, and a report of which you will most likely receive from the Secretary. I have now to request that, if you intend to publish the communication I have sent to you, you will add the following, either as a paragraph or a postscript, as you may deem most appropriate.

After a very mature consideration of the arguments with respect to the decomposition of vaccine lymph, chiefly induced by the observations of Mr. Marson, at the last meeting of the Epidemiological Society, I venture to suggest a method which, in conjunction with the tubes I have had the honour to submit to the Epidemiological Society and yourself, will, as far as chemical principles are concerned, necessarily prevent the possibility of decomposition.

It is this—simply to drop one or two minims of ordinary coal-tar naphtha into the tube previously to enclosing finally the liquid lymph, so that, the tube being filled with the vapour of this hydro-carbon, no oxygen shall be present, and no decomposition can take place. At present, of course, there is no practical proof of this: but it is my intention to put it immediately to the test, as far as my opportunities will allow; and I venture, speaking theoretically, to say, that I have no doubt that the result will be in accordance with the views I have felt bound to suggest.

#### ON COD-LIVER OIL.

By Dr. F. L. WINCKLER.

The constituents of genuine cod-liver oil, are, according to Dr. De Jongh's analysis:—

<i>Gaduin</i> ? (a so-called organic substance)	Bilifulvin
Oleic acid	Iodine, chlorine, and bromine
Margaric acid	Phosphoric acid
Glycerine	Sulphuric acid
Butyric acid	Phosphorus
Acetic acid	Lime
Fellinic acid	Magnesia
Cholic acid	Soda
Bilifellinic acid	

Hence, therefore, its composition would be quite analogous to that of the other fatty oils; but with the addition of small quantities of some of the constituent parts of the bile and also of iodine, bromine, and gaduin. But my own investigations have led me to regard cod-liver oil as an organic whole, of a peculiar chemical composition, differing from that of all other fatty oils hitherto employed as medicines. I prove this assertion by the following facts:

1. If genuine cod-liver oil from Berg (the light clear sort) be saponified with potash, and the thus obtained and purified soap be decomposed by tartaric acid, we obtain oleic and inorganic acid.

2. If a mixture, consisting of a solution of six parts of caustic potash, twenty-four parts of distilled water, and twenty-four parts of cod-liver oil, be left for several days standing at the ordinary temperature and frequently shaken, then diluted with twenty-four parts of distilled water, and distilled, the distillate possesses the most intense odour of cod-liver oil, and contains a considerable quantity of a peculiar organic compound: oxide of propyle.

3. If nine parts of cod-liver oil be saponified in a porcelain vessel, by five parts of oxide of lead in the water-bath, and the required quantity of distilled water added, the cod-liver oil is decomposed into oleic acid, an inorganic acid, and a new acid—namely, *propylic acid*. The greatest portion of this acid, as well as of the oleic and inorganic acids combine, as it appears with the oxide of lead, to form a basic compound. Another, very probably, acid salt of lead, can be extracted from the plaster-mass by washing it with distilled water. Not a trace of the hydrated oxide of glycercyle is formed on this occasion. The mass smells very disagreeably of train oil and herring, and if exposed in very thin layers in the water-bath, to the influence of atmospheric air, it assumes a dark-brown colour after the

water is evaporated, at the same time the disagreeable odour for the most part disappears.

This colourization is a consequence of the strong tendency of the propylates to become oxidized, and by this to become dark. If the solution of acid propylate of the oxide of lead be treated with sulphuretted hydrogen, and the sulphuret of lead be removed, we obtain a perfectly colourless solution, which has a strong acid reaction, becomes coloured by evaporation in the water-bath, loses the very disgusting odour of train oil, and at last leaves an intensely brown coloured residue. Exactly the same is the case with the watery solutions of the neutral propylates of baryta and ammonia. The perfectly neutral, colourless, but undecomposed solution of the ammoniacal salt smells of herrings, but that of the salt of lead smells like concentrated broth.

4. If a solution of cod-liver-oil-soap, prepared as stated in No. 3, be distilled in a suitable spacious distilling apparatus, with an addition of caustic lime and chloride of ammonium (in the proportion of six drachms hydrate of potash, three ounces of cod-liver oil, six ounces of water, six ounces of fresh burnt caustic lime, and one drachm of chloride of ammonium), with the precaution that the mixture of lime and chloride of ammonium be added to the soapy mixture previously introduced into the retort, so that the lime mixture be perfectly impregnated by the latter, the generation of hydrate of lime takes place upon the application of a slight charcoal-fire, with a rather strong heat; at the same time a colourless liquid, clear, like water, is distilled over, and this is a concentrated aqueous solution of propylamine, without free ammonia. The crystallized sulphate of propylamine is easily obtained from this solution by saturating it with diluted sulphuric acid, and precipitating the resulting salt with spirit of wine.

This very simple experiment is sufficient to prove with certainty the proportion of the oxide of propyle in cod-liver oil; the propylamine possesses all the properties of that obtained from the brine of herrings or from ergot of rye.

*Conclusion.*—Cod-liver oil, when saponified with potash, yields oleic and margaric acids, and oxide of propyle; with oxide of lead it forms oleic and margaric acids and a pure highly oxidized matter from propyle; namely, *propylic acid*. In neither case of saponification is the hydrated oxide of glycercyle obtained: the glycercyle is replaced in cod-liver oil by propyle. The generation of propylamine, on the addition of ammonia, takes place only in cod-liver oil, and in no other official fatty oil, and its place in the *Materia Medica* cannot, therefore, be supplied by any other oil.

It is not my intention to draw, from these investigations, any conclusion as to the medicinal efficacy of cod-liver oil. I am not a physician; but when we reflect that the fat assimilated by the animal organism serves chiefly as a material for the process of respiration, the possibility of cod-liver oil undergoing during this process a decomposition similar to that which it undergoes by the influence of alkalies, is very plausible; and when we further consider that in such a decomposition, by the presence of the conditions requisite for the formation of ammonia, which, indeed, are never wanting in the animal organism, the formation of propylamine is highly probable, it is not surprising why cod-liver oil alone should prove so advantageous in many diseases, even exclusive of the slight proportion of iodine; and I think myself justified in concluding that the efficacy of this oil depends chiefly upon the peculiar chemical composition which I have discovered; as propylamine, according to my experiments, is to be found also in the normal urine and sweat.

The importance of the small quantity of iodine contained in the oil I shall endeavour to determine by subsequent experiments; for the present, I shall only observe that both the oxide of propyle and the propylamine are chemically very closely related to iodine, the first forming with it a compound (iodide of propyle), similar to iodide of formyle (iodoform), which becomes very easily decomposed.—*Buchner's Neues Repertorium für Pharmacie und Phar. Jour.*

## REVIEWS AND NOTICES OF BOOKS.

**THE SPIROMETER, THE STETHOSCOPE, AND SCALE-BALANCE;** their Use in discriminating Diseases of the Chest, and their Value in Life Offices, &c. &c. By JOHN HUTCHINSON, M.D., Assistant-Physician to the Brompton Hospital for Consumption, &c. &c. London. 1852. 8vo. pp. 79.

DR. HUTCHINSON'S name is favourably known to the profession in connexion with the valuable invention for determining the capacity of the lungs, termed "The Spirometer;" and in the small volume now before us, he has given the results of above four thousand distinct observations made with this instrument upon subjects of every age, in disease as well as in health.

The object for which the spirometer is intended, we need scarcely inform our readers, is to measure the volume of air expired from the lungs; and the amount which the individual is capable of expiring after making as full an inspiration as possible, is termed the "vital capacity." The measure of this volume Dr. Hutchinson has found to be modified by the height of the individual, by his attitude, weight, age, and remarkably so by disease. With respect to height, "the vital capacity is the same (the author observes) in all men of the same stature, quite irrespective of the size of the chest; and as the height of men differs, the measurement of this volume differs, and that too in an arithmetical ratio. Thus a man of 5 feet 8 inches can breathe 230 cubic inches of air (at 60 deg. Fah.) at one expiration, and a man one inch taller, 238 cubic inches, by a similar effort. On the other hand, a man one inch shorter—namely, 5 feet 7 inches, can only breathe 222 cubic inches, being eight cubic inches less than the man of 5 feet 8 inches."

The vital capacity is influenced also by position, being greatest in the erect posture; and the author found that in his own person there was a difference of 40 cubic inches in two different positions. It is, however, in disease, particularly in thoracic disease, that the indications afforded by the spirometer are of the greatest value. Phthisis seriously diminishes the vital capacity. "This difference is not entirely due (the author observes) to the deposition of tubercular matter, for we have found that when this did not exceed a few grains, the vital capacity was deficient 47 cubic inches; yet, at the same time, it is true, that with an increasing deposition of solid matter, we have a diminishing vital capacity." From a table given in this place, the author shows that, whereas a man between 5 feet 7 inches and 5 feet 8 inches, when in health, breathes 230 cubic inches, in the first stage of consumption his vital capacity is only 154 cubic inches, and in the second stage 108 cubic inches. "We often find (Dr. Hutchinson observes) a deficiency of 33 per cent. when only those morbid stethoscopic sounds are heard which indicate the friction-sound of air in the tubes to be changed: as harsh or feeble respiration, instead of the soft vesicular murmur, which gives the healthy volume."

The author next describes the spirometer, and the manner of using it, accompanied by figures of the several forms of the instrument. In the second part, under the head "Stethoscope," Dr. Hutchinson gives a condensed account of the healthy and morbid sounds heard on auscultation of the lungs.

The last part is addressed to the medical referees of life assurance offices. "The knowledge required by a medical man in the 'life office' and in the consulting-room is very different (the author observes); in the consulting-room the patient is full of complaints, ready to acknowledge all the symptoms of disease which he may experience; but in the assurance office, generally, the applicant acknowledges no complaint, he wishes to appear free from all diseases. In the consulting-room no information is withheld; in the life office the tendency is to withhold, or keep back, certain information; and here it is for the medical officer to sift out and de-

tect the existence of any condition which may tend to shorten life."

"It is now a custom in life offices to furnish a printed form of questions to be filled up by their medical officer. Questions are all-important, and questions must be asked of the applicant; but too often there is a long and needless list given to the medical officer. We have seen such a paper contain 101 questions, terminating with another demand of the referee's 'private impression' of 'anything else to be suspected.'"

This is injurious to an office; no man likes to answer a number of personal questions; moreover, the manner in which they are answered, particularly by writing, is generally cursory and vague: the office, in reality, is not more safely guided by the mass of questions.

An assurance office should rest upon the judgment of their medical men, and not upon the long printed list of questions; if the former cannot be depended upon, neither may the latter. An applicant for assurance visits an office, and it is for the medical officer to sift out in the most delicate manner, is this a 'good life,' or is it not so.

Let our printed questions be few—to the point, and let each one be well considered; indeed, we are disposed to think that they may all resolve themselves into—

1. What is the family history?
2. What are the habits of life?
3. What is the height and weight?
4. What illnesses since childhood?

These few questions, when well examined and judiciously considered in all their bearings, are sufficient for the protection of a life office."

Each of these subjects of inquiry is then fully illustrated; and this part is accompanied by numerous statistical tables bearing upon the more important questions.

Dr. Hutchinson's little work contains within a small compass much useful information, indispensable to all who desire to make a practical use of the spirometer. The author has also thrown together some valuable hints for the benefit of the medical referees of life insurance offices; we should like to see this part of the subject continued and extended; no one seems to be more capable of doing it justice than the author, and we think he would confer a benefit upon all who are engaged in such inquiries if he would undertake the task.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JULY 21, 1852.

## PERSONAL DIFFERENCES OF MEDICAL MEN.

WE have already expressed our regret that our columns should be found to contain matter painful to the feelings of two respectable members of our profession, and have taken blame to ourselves for having inadvertently been, to some extent, the cause of the publicity given to the dispute. We have this day to lay before our readers two more letters on the subject (we hope the last), and to express a hope that we shall not again have to apologise for a similar error. Not that we are at all squeamish as to our notions touching the "freedom of THE PRESS," or as to the inviolability of the characters of the members of our body, but because comments on alleged infringement of rules of medical ethics should, if possible, be restricted to cases involving general interests only. Between the two gentlemen who have appealed to the profession through our columns, it is impossible for us to interpose, lest we should be considered to give a tacit sanction to some principle which we might not approve. When public men lay hold of public institutions, public measures, and public interests to gain their own private ends exclusively, we acknowledge no obligation to refrain from bringing them before the bar of public opinion personally and by name; but where the

question is of a more private nature, it is otherwise. In that case the parties concerned are the proper persons to handle the matter, and we have only to take care that they do not handle it too roughly. We have often in the course of our editorial labours been amused at the virtuous indignation expressed by some gentlemen and their friends when we have expressed our doubts as to the correctness of their views respecting public questions, and the justice of their acts in accordance with such views. They fall into towering gusts of rage when their "motives" are impugned, and denounce us in no measured terms for daring to suggest doubts which they themselves anticipate. Fortunately, however, we have discovered that our editorial excesses in this respect are not such an usurpation of authority as might be supposed, seeing that our brethren, in dealing with each other, often exceed the bounds which we assign to our remarks. Even the case before us, although we have expressed our regret as to its occurrence, will probably operate beneficially, by showing how such cases affect general interests, and how liable such are to arise if great caution be not adopted. So intense is the competition between members of our body, that differences amongst them must take place daily, and the great aim should be, to let them pass with as little aggravation as possible. One of the most successful and respected of Dublin Surgeons had a saying, by means of which he often succeeded in throwing oil on the troubled waters. When a junior complained to him of ill-treatment by a brother practitioner, and sought his counsel as to the best method of retaliation, his reply generally was, "do you want to go through the world like a skinned eel?" And so it is; for if any man feels all the rubs which he necessarily encounters, he will lead but a very uncomfortable life of it. We have heard of another equally successful Dublin Practitioner's method of comforting his own son when he told him how he had been accused of killing one of his patients. His observation was: "How often have you had credit for curing cases without the slightest claim to it? Put one item against the other." It is true that cases must occur which flesh and blood cannot tolerate, but they are not of frequent occurrence, and may be dealt with better in a quiet way. What would some of our thin-skinned folk think of a competitor, or of his adherents or followers, who make it a practice to circulate reports leading to the conclusion that men are incapable of practising from age and infirmities, or that they had retired, or left the country? Yet such are found; and not only so, but applauded for their cleverness. The truth is, many simple members of our body have yet to learn that there is more of leave and licence amongst us to talk and act than is generally supposed:—

#### TO THE EDITOR OF THE MEDICAL PRESS.

MY DEAR SIR,—I beg leave to preface this communication by one or two explanatory observations. In the first place, I am perfectly sensible how little the professional public care for Dr. Lynn's and my private differences, and painfully conscious that we most unjustifiably occupy your valuable space, and cover ourselves with deserved ridicule by giving expression to them in the PRESS; secondly, your readers will be good enough to observe, that Dr. Lynn, having left his unfortunate case to speak for itself, has taken refuge in pitiful personalities, in which, for the first time in my life, I find myself accused of want of taste, want of temper, and want of truth—a climax of accusation more than sufficient to justify this rejoinder, and that on him consequently rests the entire blame of this prolonged trial of your and their patience. Without further preface, I shall give you the plain unvarnished history of the apology referred to, and of which Dr. Lynn's

last most extraordinary production furnishes such a meagre outline and such a distorted version.

On Wednesday, the 9th of June, I was called upon by Dr. McMunn, the lately appointed governor of our District Lunatic Asylum, a gentleman with whom I have been for fourteen years on terms of intimacy, and latterly of cordial friendship, to know had I stated that "Mr. Harrison was dying of consumption, and that he (Dr. McMunn) had been *killing him*." "Who is your informant?" I replied. "Dr. Lynn," was the rejoinder. I immediately sat down, and wrote the following letter:—

(No. 1.)

"Sligo, June 9, 1852.

Dr. Little presents his compliments to Dr. Lynn, and requests that he will be good enough to furnish Dr. Little with the name of his informant, 'that Dr. Little had stated that Mr. Harrison was dying of consumption, and that Dr. McMunn had ill-treated him:' the utmost publicity will be given to this scandalous fabrication, its source, and Mr. Harrison's emphatic denial of it, if a distinct and satisfactory explanation is not at once afforded."

This is the letter which Dr. Lynn designates as "very intemperate." Compare it with the provocation received, and I think any right-minded person will call it far too mild and forbearing. To this the following gentlemanly reply was sent in the course of the day:—

(No. 2.)

"'Dying of consumption' was not a part of the statement. For what Dr. Lynn did state, Mrs. Vernon Davys was his authority, Mr. Harrison having to Mr. Vernon Davys so expressed himself on the preceding evening: Dr. Lynn thought it right to mention the circumstance to Dr. McMunn as to a professional brother."

On this tasteful, well-tempered, and truthful production, I have to remark, that the very words used to Dr. McMunn, and subsequently, *but with much difficulty*, admitted by Dr. Lynn when pressed by Dr. McMunn, were, that I had stated Mr. Harrison "was dying of consumption, and that Dr. McMunn was killing him." From Mrs. Vernon Davys' letter of explanation, a copy of which I possess, and which was referred to at the arbitration, also from Mr. Harrison's letter of emphatic denial, which I hold, and which is equally public, and from a long personal interview with Mr. Vernon Davys, it appears that Dr. Lynn had not the shadow of a shade of a warrant for this strong language, and in fact that it was a mere piece of malicious invention. The spirit in which the communication was made to Dr. McMunn is best shown by the extraordinary fact, that on receiving my first letter he followed Dr. McMunn to the workhouse, and asked him "reproachfully (this is Dr. McMunn's own term) why did you tell Dr. Little the purport of my communication to you this morning?"

Naturally irritated by such a reply, I wrote the following, which I joyfully embrace this opportunity of making public:—

(No. 3.)

"Sligo, June 10, 1852.

SIR,—I received your attempt at an explanation yesterday on my way to Tubbercurry, from whence I have but just returned. As on more than one former occasion, it far from improves your position; and, as usual, endeavours to avoid the truth by mere verbal objections to an unimportant part of my charge. If you consider it upright professional conduct to pick up an uninvestigated slander of one medical man, and repeat it mischievously to another, with the design of creating ill-will and mistrust between known friends, you are peculiar in your notions of medical ethics, and I am happy to think will not find one gentleman in the profession to agree with you. I send a copy of Mr. Harrison's emphatic denial of the observations attributed to him; with Mrs. Vernon Davys I have nothing to do, nor is it my intention to take the least trouble to endeavour to reconcile the discrepancy between her version of the story, Mr. Harrison's, and yours. The only course to adopt with this unmanly system of 'stabbing in the dark,' is full and complete exposure. If, therefore, in the course of the day I am not furnished with a full and satisfactory written apology or expression of regret for the prominent part you have taken in the repetition of this cowardly and malignant falsehood, I shall lay the whole matter before the public, and in particular before every friendly brother in the county, with such comment on this and other parts of your conduct as I shall see fit.—I am your obedient

WILLIAM S. LITTLE."

After two or three days vainly spent by my friends and his own in endeavouring to point out to Dr. Lynn the propriety

and necessity of his apologising, I consented (for the proposal came from Dr. Lynn, though he so absurdly attributes it to me, when every one of the arbitrators can state the contrary) to an arbitration, when the matter was, as we all imagined, arranged by the following letters; my friends reserving for me full liberty to make what use I pleased of them, though Dr. Lynn states, in *italics*, that an understanding was entered into that the subject should "never again be alluded to by either of us," which I most emphatically deny, and defy him to substantiate by any evidence whatever:—

(No. 4.)

"Sligo, June 14, 1852.

SIR,—I beg to express my regret that you did not consider my reply to yours of the 9th satisfactory or courteous. It was not intended by me to give offence.—Yours obediently,

(For)

ROBERT LYNN.  
FRANCIS Y. GILBERT.  
THOMAS YEATES."

To Dr. Little.

(No. 5.)

"Sligo, June 14.

SIR,—In reply to yours of this date, I have to express my regret for having written to you my letter of the 10th inst. It was written under feelings of excitement, after having received yours of the 9th, and I now beg to withdraw it.

(For)

WILLIAM S. LITTLE.  
NOBLETT R. ST. LEGER.  
HENRY GRIFFITH."

(No. 6.)

"Sligo, June 14, 1852.

SIR,—Having read a letter from Mr. Harrison not bearing out the truth of a statement I made to Dr. McMunn respecting you, in reference to his treatment of Mr. Harrison, I have no hesitation in expressing my regret for having mentioned to Dr. McMunn what (before Mr. Harrison's letter of denial) I believed to have been true.—I have the honour to be, sir,

(For)

ROBERT LYNN.  
FRANCIS Y. GILBERT.  
THOMAS YEATES."

You will be good enough to observe, in reference to the foregoing correspondence, that the letters marked Nos. 4 and 5, are entirely extrinsic of the original matter in dispute, and as far as it is concerned, are of no manner of importance. With what taste, temper, and truth Dr. Lynn has presumed to send you those two, and to remain entirely silent on the subject of No. 6, I leave you candidly to determine.

Dr. Lynn has stated that a proposition was made by him, and he *believes* conveyed to me, that I should see his case. Will Dr. Lynn be good enough to state when or to whom such a proposition was made, as I solemnly protest this is the first I ever heard of it; but in point of fact, Dr. Lynn's entire letter is such a tissue of prevarications and *suppressiones veri*, that there is hardly one line of it which does not more or less commit him grievously in the very respects in which he has asserted me to be so deficient. Had he made such a proposal, I should in courtesy have acceded to it, not in order to be convinced that wrong was right, or black white, but as an opportunity afforded me for the inspection of such a surgical curiosity, as the officer who carried about in his brain for two years the breech of a double-barrelled fowling-piece, and others of a similar kind.

Upon reading Dr. Lynn's last letter, I immediately put myself in communication with my professional friends in the towns selected by Dr. Lynn as the imaginary theatres of my many professional squabbles. I have as yet only had time to receive (through cross posts) one most satisfactory reply. When they arrive, I must, in justice to myself, demand their publication in the Press after the next. I repeat, in the most emphatic manner, that I never, in the whole course of my existence, had one word of dissension with a medical gentleman anywhere on a professional subject.

For my friendly, and more than friendly relations with every gentleman in this county (with the single exception of Dr. Lynn himself), I refer to the following respected names, as those alone with whom I have had the slightest degree of professional connexion, in the way of consultation or otherwise—namely, Drs. Carter, Homan, O'Ferrall, McMunn, Wood, Kelly, Armstrong (sen. and jun.), Lougheed (sen. and jun.), Hamilton, Powell, Vernon, Allingham, and Johnstone. To each and every of these gentlemen, I refer with the utmost confidence that I shall be more than borne out by them.

What, then, I ask, is the object, where the foundation of these libellous aspersions on my character? Where are the temper, taste, and truth of the man who rushes into print with only such crude, and clumsy, and laughable fabrications in reply to what? A simple critique upon his practice! What on earth does he ~~mean~~ by summoning the MEDICAL PRESS

and the public papers as part of his evidence? The only correspondence of mine in the Press, or any professional periodical not strictly *medical* (save this), was my correspondence with the vice-guardians of Tuam and the poor-law commissioners, for which I received letter after letter of congratulation and compliment from over fifty men of the profession in various parts of Ireland; and the only matter in the public papers was a series of four letters between myself and Dr. Waters of Birr (whom I have never seen in my life but once, twenty-three years ago, when we were fellow apprentices of the late Mr. Carmichael), on the subject of the Medical Charities Act, and I have yet to learn that a controversy on the policy of an act of parliament is to be tortured into a private quarrel.

Dr. Lynn is perfectly welcome to quote my private and confidential letters, obtained under false pretences, from a third person. I should not care if any such were posted on the courthouse doors.—I am, dear sir, yours faithfully,

WM. S. LITTLE.

Sligo, July 10, 1852.

A few days before the receipt of the above, we received the following from Dr. LYNN, and in compliance with his request we append it:—

TO THE EDITOR OF THE MEDICAL PRESS.

MY DEAR SIR,—I trust the Sligo correspondence will now be at an end. If, however, there is any more of it, I must, in the first place, beg of you to correct one or two errata in my letters. The word "him" alters the force of the letter dictated for Dr. Little; the sentence should be—"one for Dr. Little, expressing regret for his letter of the 10th, as written under feelings of excitement, &c., and begging to withdraw it." The word "humble" instead of "desirable" enjoyment, is not worth alluding to.—I am, very sincerely, yours,

ROBERT LYNN.

## DIRECTIONS FOR THE ARBITRATION.

In the first place, to read the letters and statement connected with Captain Moriarty's case. The intemperate attack on me for doing what any medical man under the circumstances should do—namely, when accidentally within a few yards of the house, and hearing that Captain Moriarty was still alive (Captain Moriarty was my patient: Dr. Little had been feed'd and dismissed), four hours after he was reported dead, calling in. Even after finding out his error from Mrs. Moriarty herself, Dr. Little refused any apology to me in a letter still more violent, &c.

2. The letters or the extracts referring to Lady A.—. This, the turning point of any subsequent want of courtesy on my part, must come out. Is Dr. Little prepared to apologise for that "stabbing in the dark?" His own words. I could have looked on all connected with Captain Moriarty as arising from mistake, or as an exhibition of temper, &c., and made allowance for it.

It will not do to say it was marked "private;" that would be still more "stabbing in the dark," and will not justify the circulation of such falsehoods. Dr. Homan (for I showed the letters to some members of the profession) will bear testimony that the extracts are according to what he saw in the original; he might be asked his opinion of them. Even if the statements were true, there can be but one opinion among medical men.

3. His uncalled for attack on me in the MEDICAL PRESS. Was it gentlemanlike, or in good taste, to hostilely criticise the treatment of one on such terms with him as I have been since Captain Moriarty's affair? What had he to do with it? Had he seen it? was it to reëxcite all the angry feelings again, or was it simply because he was not called in? Had it not been for that case I would not have seen Dr. McMunn or made any communication to him that day; but what, after all, did it amount to? Simply to this. That having heard a report disparaging to a medical brother, I mentioned it to him as a *privileged communication from one medical man to another*, and thus gave him an opportunity of clearing himself. The statement made to me, on investigation proved to be incorrect; but when applied to for my authority I gave it up. I regret I did not do so with more courtesy, and expressed my regret for having mentioned to Dr. McMunn what proved on investigation to be untrue. Dr. McMunn had acted with similar kindness to me, when a few hours after Dr. Little had seen the late Mr. Christian with me, Dr. Little's friends were circulating the report that I had mistaken his complaint, and that Dr. Little had discovered what

had escaped Dublin doctors and all! Dr. McMunn very properly put me on my guard. I have never had the slightest misunderstanding with any other medical man in our professional attendances; but we have always cordially and in good faith united for the benefit of our patients, not fearing that our motives for a kindness should be misconstrued, &c. Dr. Little had differences with Drs. K., H., and McM. It is painful to bring in the names of other medical men, but in self-defence and a private investigation; nor have I quarrelled with private individuals. Finally, I am willing that Dr. Little and I should both pledge ourselves never to mention each other's names, on paper or otherwise, except to a medical man, and that as seldom as possible; secondly, to salute each other in the streets, that the public may know nothing of professional differences; thirdly, I think we owe it to the public not to decline meeting in consultation, and advising to the best of our abilities for the benefit of the patients. If Dr. Little desires more than this, he must first get me out of the difficulty about answering his criticisms on my case, for I must begin by denying on the part of my medical brethren and my own, that the "great majority of such cases, whether in or out of the infirmary, pass through his hands." I will, with Dr. Homan who saw the case, explain more clearly than I did in my report, and I will call with him on the patient, and Dr. Little can then say, "that having heard more particulars he is satisfied the treatment was justified." He should also express regret for some older matters, and for the violent language he used in his letters, sufficient to prevent explanations when called for. Captain Moriarty's case could in the simplest way have been explained, if explanation had been kindly asked for. What need is there to speak in one's family on medical matters or medical differences? Mrs. Lynn did not know of Dr. Little's Moriarty-quarrel with me for months after, or know that Miss L. and I did not speak for a year and a half; and she would not have known of this last unpleasant affair only for Mr. St. Leger's calls at my house, coupled with my anxiety of mind at the trouble and vexation I have been the cause of in the family of Mr. Davys.

ROBERT LYNN.

*Extracts from Letter referred to No. 2.*—"During my father's illness, Dr. Lynn attended her once in a miscarriage also, when he suffered a second foetus to remain in-utero for thirty-six hours; knowing nothing about its existence, and having taken no steps to ascertain it, till after an almost fatal hæmorrhage it was expelled by the natural uterine efforts. During this period he was walking about the room in a state of distraction, wringing his hands, and crying out that he would give a thousand pounds that Dr. Little (the elder) was in attendance." If this has to come before the public, what will the "conscript fathers" think? In a subsequent miscarriage the lady was attended by Dr. Little, and died. On that occasion Dr. Little told me he would give a hundred pounds he had never come to Sligo.

I have had a very extensive midwifery practice in Sligo (not, however, in the proportion of 99 to 1), and never lost a midwifery patient (to whom I had been previously engaged), otherwise such a falsehood (which was circulated to my prejudice in Dublin, Mayo, Leitrim, &c., but which I never expected to see under his handwriting) would have done me serious injury. What courtesy did I owe him after that letter coming to my knowledge?

### OBSCENE ADVERTISING.

We have not for a long time been directing the attention of our readers to this lamentable chapter in the history of the present generation, hereafter to be written, because we found the effort to divert the reproach hopeless and useless. Then, these disgusting evidences of the moral and religious tone of mind of society, as it now exists, must serve to justify the sentence of the historian. How many parents will respond to this appeal? how many will forbid the perusal by their children of beastly allusions to "the secret infirmities of youth," "the physiology and functions of marriage," "the treatment of spermatorrhœa," "generative debility," "excessive indulgence," and "preventive lotions?" How many will throw the newspaper in the fire when a little daughter inquires: "Pa, what is *fluor albus*, or falling of the womb, or syphilis, or stricture, or urino-genital disease?" all which she finds set forth

on the scrap with which she curls her hair. Here, however, is the appeal to which we allude, cut from the columns of the *Times* newspaper:—

I am the rector of a rural parish—the father of a family. I am one of those who have acknowledged in many ways the value I set on those periodical publications which have appeared of late years, conveying instruction while they afford amusement. For my present purpose, I particularize the *Household Words*, edited by Mr. Dickens—a work I have ever felt to be a great acquisition where there are young people in a family. With scarce a glance at its "contents," I had hitherto no fear in handing it over to the perusal of my own daughters. Conceive then my disgust when, having just taken up the last number of that periodical, on proceeding to cut the leaves, I found the printed slip I enclose placed artfully between them. With some experience of the world, I can truly say it never was my ill-fortune to see anything more morally filthy, more grossly indecent, put into print. To make the matter worse, it professes only to give to you the subject-matter of a work, to be had by post for two shillings, which work is to give, in Latin and English, all the foul detail of which this advertisement is only a synopsis. I applied at once to my bookseller—a most respectable man—to know how this detestable thing got where I found it. He tells me it is placed in many of those periodicals in London, and he has ever torn it up when he could discover it. How are fathers of families to be guarded from this evil? And the worst of it is, that it is clear that the thing itself is the offspring of what, forsooth, is called a religious movement; as such, we may yet see such things placed in the leaves of the Bibles we may order to give away. I can only hope now, by your permission, to warn fathers and mothers of families, that they may take what steps they can in the matter. We can watch our books, or leave them off; I see not what else we can do. But I entreat of you to use your all-powerful voice to check this disgusting practice. I enclose to you the identical slip of printed paper of which I have spoken, and other proofs in the matter: they will speak for themselves. [The printed slip referred to has been forwarded to us by our correspondent, and we can bear witness to its being most filthy and indecent.—*Ed. Times.*]

Since the above was put in print, we have found that the "filthy and indecent" slip alluded to was not one of the obscene medical advertisements, but something just as bad. So we leave the matter as it stands, allowing those whom the cap may fit to wear it.

### MEDICO-LEGAL COLLOQUY.

MEDICAL CERTIFICATES AND EVIDENCE.—Rachel Evans was brought before Alderman Farebrother, at Guildhall, charged with cutting and wounding Sarah Cook, with intent to do her some grievous bodily harm. It appeared that the complainant and the prisoner were quarrelling, when the latter struck the former on the forehead with some sharp instrument, which she thought was a knife, and inflicted a wound over the left eye. She was taken to the hospital, where her head was dressed and strapped up. A certificate from the house-surgeon of St. Bartholomew's Hospital was here put in, stating that "Sarah Cook was admitted, suffering from a lacerated scalp wound." Alderman Farebrother—Take this certificate back to the surgeon, and tell him he must attend himself, or write something that is intelligible; we know as well as he does that the woman is suffering from a lacerated wound in the scalp. Take a summons, officer, and if the surgeon refuses to come, bring him with you. In a few minutes the surgeon arrived. Alderman Farebrother (to the surgeon)—We could save you a deal of trouble by dispensing with your services if you would only send us an intelligible certificate. Surgeon—I thought it unnecessary to state anything else on the certificate, knowing you could judge of the nature of the wound from the appearance of it. Alderman Farebrother—That may be very true; but the information we require for our satisfaction is, as to the kind of wound, what weapon it was probably inflicted with, and if it was likely to be attended with any dangerous results. Surgeon—It shall be done so for the future, sir; with regard to the wound received by the complainant, I should say it was not inflicted with a knife or any sharp instrument. Alderman Farebrother—Then it is your opinion that the wound might have been caused by a water-pail, as stated by the prisoner. Surgeon—Certainly, sir. Alderman Farebrother—I regret

being obliged to trouble you, but you have brought it on yourself, and I hope I may not have to send for you again. [Though the remarks of the magistrate in this case may appear hypercritical, it cannot be too strongly impressed upon the minds of our brethren, particularly the junior members of the profession, to use no technical language in certificates, or in giving evidence. The language should be plain, clear, and explanatory. The medical witness is called upon for his opinion of the nature of the probable consequence of the injury, and he must not leave the appearance to be judged of by those sitting to administer justice.—*Ed. Lancet.*]

### ON THE MERITS AND DEMERITS OF THE OVARIAN SECTION.

THE following are the conclusions which the "British and Foreign Medico-Chirurgical" Reviewer arrives at after a careful consideration of the whole of the cases bearing upon this point, although they must only be considered on the whole as approximations to truth:—

1st. That in any case in which it is considered advisable to remove an ovarian tumour, it is justifiable to make a small preliminary incision into the abdomen, for the purpose of determining whether the tumour be adherent or not.

2nd. If the tumour be adherent, the incision is to be immediately closed entirely, or to such an extent as merely to leave an aperture the size of that made by an ordinary trocar, and we may then expect that this operation will not, on the average, be followed by much more fatal results than common tapping.

3rd. That where the tumour consists of a simple cyst or cysts, with but small solid deposit, it may be extirpated with as good a chance of success as attends the performance of the more serious surgical operations, and with the further prospect of the cure remaining permanent.

4th. The existence of much solid deposit, or of extensive adhesions, absolutely forbids the operation, which should be brought to a termination immediately on the discovery of either.

Finally, we may add our belief, that the plan proposed by Mr. Wilson, of tying each bleeding vessel separately, so as to dispense with the ligature round the pedicle, is an important improvement; and that, if experience show that it is sufficient for the cure of the disease to remove only a part of the cyst, the operation will be rendered considerably more hopeful.—*Brit. and For. Med. Rev.*

### ON DISLOCATION OF THE THUMB.

M. Roux's method of reduction.—M. Demarquay has published in the *Bulletin de Thérapeutique*, certain experiments of his which were undertaken to ascertain the actual state of parts in luxation of the thumb. The case which directed M. Demarquay's attention to the subject, is the following:—

A lady, in leaving her carriage, fell upon the pavement with outstretched arms, and a dislocation of the thumb ensued. M. Demarquay thus describes the state of the parts:—The thumb was forced backwards, and formed an obtuse angle with the corresponding metacarpal bone, whose phalangeal articulation projected under the muscles of the thumb. The ungual phalanx was flexed, and all movements of further flexion or extension were impossible. M. Demarquay used all known means of reduction without success, and M. Roux was called in previous to muscular secretion. The latter surgeon used the same tractions as had before been done; but before flexing the thumb he rotated it inwards, whilst he made forcible flexion, and reduction was thus obtained.

M. Demarquay was struck with this result; he made several experiments on the subject, and found that in a complete luxation of the thumb backwards, the following changes take place:—The metacarpal extremity of the first phalanx comes to rest on the posterior portion of the articular surface of the first metacarpal bone; and the phalangeal extremity of the latter projects under the skin, after having passed through the two portions of the flexor brevis pollicis, the external portion being frequently torn. This phalangeal extremity of the first metacarpal bone is thus caught in a loop formed externally by the outer part of the flexor brevis and the adductor, and internally by the inner portion of the flexor brevis, the adductor pollicis, and the strong tendon of the flexor longus pollicis. That these are really the phenomena which take place has been ascertained by the experiments of Messrs. Pailloux, Vidal, Malgaigne, Lisfranc, and Laurie.

Inspections of individuals who have died with this luxation, have shown besides that the anterior ligament is always ruptured close to the metacarpal bone, and that it is carried along with the posterior portion of the luxated first phalanx. As in the above-mentioned experiments both lateral ligaments, or at least the external, were always ruptured, the theory of Dupuytren and Rey falls to the ground. If then the difficulty of reduction cannot be ascribed to the persistence of the lateral ligaments, nor to the force of the anterior ligament, the main obstacle must lie in the muscular loop, which is slung round the head of the metacarpal bone.

In summing up, M. Demarquay gives the following rules: 1st: To use a sufficient amount of traction (with Charrière's forceps) on the luxated bone, in the direction of the axis of the thumb. 2nd: To push back with the operator's thumb, or left index-finger, the head of the metacarpal bone, and keep it quite steady, so that when flexion is made, the head may not be thrust further into the palm of the hand. 3rd: When extension is carried to a sufficient extent, rotation either towards the outer or inner side should be made, so that the head of the metacarpal bone may be freed from the muscular loop which is keeping it strangulated. This being done, the traction should be continued until the posterior part of the first phalanx has reached the level of the head of the metacarpal bone. Flexion is then to be made, whilst at the same time the left thumb of the operator forces backwards the displaced part of the first metacarpal bone.—*Lancet.*

## ORIGINAL COMMUNICATIONS.

### THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. FREKE, A.B., M.B., M.R.I.A.

(Continued from page 391, Vol. XXVII.)

(The Function of Nerves continued.)

In my last communication I was desirous of attempting to investigate as a general question (that is, applicable to all varieties of nerves indiscriminately) the following, as I regard it, not unimportant inquiry—viz., "What is the nature of the specific physiological function of nerves?" I say nature of that function, inasmuch as such (in conformance with the plan or arrangement laid down for the present inquiry) constitutes the first question proposed for investigation in relation to the function of nerves.

Before proceeding to the consideration of the second division of the inquiry directly before us—namely, the second question proposed for investigation in relation to "the function of nerves;" that is, in other words, before attempting to inquire into—2ndly, "the provision or arrangement which has been adopted by Nature whereby nerves shall be caused (in a normal or natural manner) to discharge or develop that function;" before, in a word, searching for the several varieties of specific stimuli provided by Nature for the several varieties of nerves in existence, it will, as I regard it, be desirable (for perspicuity, and that my subsequent observations may with facility be intelligible to all) to occupy a moment of the reader's attention with one or two well-established general facts in relation to the anatomic construction of nerves. It will, in other words, be conducive, as I regard it, to perspicuity and clearness, briefly to lay distinctly before the view of the reader one or two facts which have been well established, and are generally recognized, in relation to the several distinct component parts (and their functions respectively) which, upon an

anatomic examination of the nervous system of man, are invariably found as constituents of his nerves.\* I have been led to regard it as desirable, in this place, to direct the reader's attention to these facts, from a feeling that is of moment to the general inquiry at present before us, and to a clear recognition of the full bearing of my subsequent observations, that he should keep distinctly and clearly before his mind that general plan or arrangement adopted by Nature in the anatomic construction of human nerves, to which I am now about to recal his attention.

A nerve (as the reader is already aware) is composed anatomically of two distinct parts. In other words, each nerve may be divided (as regards its first or primary anatomic division) into two component or constituent parts essentially distinct in the nature of their anatomic construction.† To the one of these parts (from the peculiar vesicular nature of its construction) anatomists have given

\* The reader will please to bear distinctly in mind that, throughout these observations, I refer exclusively to the nervous system of man, without any reference whatever to such modifications in the general anatomic arrangement of nerves as may be found in some of the lower orders of animals. It is (as the reader is doubtless already aware) the opinion of some physiologists that, in certain of the lower tribes of animals (in which anatomists have yet been unable to demonstrate the existence of nerves), that nervous matter exists, "diffused," in some way, through the other tissues of which such animals are composed. Upon (what to me might appear to be) the probability or otherwise of such being the fact, I here express no opinion whatever, but confine my observations, for the present, exclusively to the plan or arrangement which we see to have been adopted by Nature in the anatomy of the nervous system of man.

† I have used the words "first or primary" anatomic division in the above paragraph, inasmuch as I do not consider it necessary at present to occupy the reader's attention with inquiries into the ultimate or minute anatomic composition of nerves; that is, in other words, it not being essential, as I regard it, to a clear exposition of the question before us, to investigate how far the ganglionic and the fibrous portion of a nerve may, either or both, admit anatomically of being subdivided into different structures, I have not considered it desirable at present to contemplate such question.

the name of the vesicular or *ganglionic* portion of that nerve. The other (from the nature of *its* constitution) has been designated the *fibrous* portion of such nerve. These two parts in conjunction (*viz.*, "*ganglionic*" and "*fibrous*") constitute what we understand by "*a nerve*." Now, this natural division of one and the same individual nerve into two anatomically different parts, implies that *each* part has some duty to perform which is *peculiar* to itself; that is to say, in other words, this distinction in construction implies distinction in function. We are hence called upon to inquire into the nature of this latter distinction, or (which amounts to the same thing) we are led to ask, What is the nature of the *relation* in which these two distinct parts of a nerve stand towards each other? In other words, a recognition of Nature's division of a nerve into two distinct parts at once suggests the following question—*viz.*, What is the *special* part performed by *each* individual portion of a nerve while contributing *its share* to the *general* function of that nerve? This question has received a satisfactory reply, with the contemplation of which I would now, for a moment, occupy the reader's attention; and first, as to the "*ganglia*" of nerves.

The ganglionic portion of a nerve (as the reader is already aware) is that wherein is originated or developed, or (if the term "*generation*" so employed be not regarded as inappropriate) wherein is *generated* that agency or principle (whatever it be, or whatever be its nature) to which physiologists have given the several names—*nervous "influence," "agency," "principle," "force," &c.* It matters, as I regard it, but little (provided always we connect *no hypothesis* with the expression we employ) which term we select to express simply this—*viz.*, the *unknown cause* of recognized results. That to *generate* or *develop* such nervous "*influence*" or "*force*" is the special duty or function of the *ganglionic* portion of a nerve is, I believe, the opinion universally entertained by physiologists. The same statement may for perspicuity be otherwise expressed in these words—*viz.*, in the *ganglionic* portion of a nerve is *developed* or *generated* that agency (whatever it be) which, on exercising its influence upon some organized structure anatomically connected with nerves, *stimulates* (as was my effort to make apparent in my last communication) that structure to the discharge of its physiological function. If such be the acknowledged function of the *ganglionic* portion of nerves, the following question will naturally suggest itself to some minds—*viz.*, What *necessity* can there be then for the *additional* element referred to—namely, that termed the *fibrous* portion of nerves? I shall explain myself more clearly. If (as is I believe universally acknowledged to be the fact) the specific physiological function of the ganglionic portion of a nerve be to develop or generate that agency or principle which we designate nervous "*influence*" or "*force*;" and if (as I endeavoured to make apparent in my last communication) the specific function of that "*influence*" or "*force*" (when its generation has taken place) be to *stimulate* to the discharge of its physiological function some other organized structure (*i.e.*, distinct and apart from that nerve) placed by Nature in anatomic connexion with nerves; if it be true that these two statements are facts, then, I say, it might naturally suggest itself to the mind of some of my readers that, in "*ganglia*," we must have *all* that can be required of a system of nerves, inasmuch as all that can be required is nervous "*influence*" or "*force*." That "*ganglia*" *alone* (since *they* can *develop* that required nervous "*influence*" or "*force*") should be adequate of themselves, without any additional element, to constitute a *nervous apparatus*; in a word, that a "*ganglion*" is essentially "*a nerve*." Why, then, we may naturally ask, if such be the case, is there a necessity for an *additional* element? Wherefore is it that that ganglion, without the superaddition of a separate structure, is not competent to discharge the *entire* function of nerves? Why is it that the second anatomic

division above referred to is *invariably* found to constitute a component of our nerves? In a word, *what* is the *function* of the *fibrous* portion of our nerves, or wherefore is it that there is a necessity for *its* existence? The function of that portion has, in like manner, been satisfactorily learned, with the nature of which function I shall occupy but a very few moments of the reader's attention. The function of the *fibrous* portion, in the case of *some* nerves, is *twofold*; or in other words, *some* nerves require for the discharge of their function *two distinct fibres*. The necessity for the provision of one or both of such fibres, I shall now attempt to place concisely and distinctly before such of the readers as may possibly not have perfectly clear views upon the subject.

As its "*ganglion*" may be regarded as constituting the (more indispensably) *essential* portion of a nerve, I shall (for a moment, for the sake of perspicuity) regard that ganglion as constituting the *entire* nerve. Let us now contemplate any such ganglion or nerve in two altogether distinct relations which, we are aware, every such ganglion or nerve must of necessity have been placed in by Nature; that is, let us contemplate such ganglion or nerve—1st, in its relation to that agency, object, or entity (whatever it be, or whatever be its nature) by which that ganglion or nerve is *itself* to be stimulated to the discharge of its function; and 2nd, in its relation to that object (*viz.*, the organized structure with which it has been placed by Nature in physiological contact) upon which that ganglion or nerve has to exercise or discharge *its own* physiological function (*viz.*, that of *stimulating* such organized structure to the discharge of its function). I trust I convey myself clearly. Lest, however, it should be otherwise, I shall endeavour to be more explicit. The specific physiological function of a nerve is (as I attempted to make apparent in my last communication) to stimulate to the discharge of its physiological function some *other* class or order of organized structure (such, for example, as that structure we name "*voluntary muscle*") with which that nerve has been placed in physiological contact. But that nerve, in the discharge of that physiological function, has been *itself* made in all respects subject to identically one and the same *general* arrangement or law (*viz.*, with regard to the *requisites*—that is, the required conditions—for developing function), as the muscular fibre, or other structure with which such nerve is connected. That nerve, in common with muscular fibre and with *all* organized residual products which develop phenomena of animal life, requires (in addition to the operation of some general cause—namely, an incidental stimulus, *viz.*, oxygen gas) the presence and operation of some *specific* cause of the disturbance of its condition of quiescent vitality and consequent manifestation of its physiological function. In a word, that nerve, in common with all organized structures which develop a vital phenomenon, demands the operation of some *specific* stimulus which is competent to *cause* it to develop such phenomenon. Hence it is obvious that *some* object, agency, entity, or attribute (whatever it be, or whatever be its nature) *must* of necessity have been provided by Nature, to which she has imparted the faculty or function, or upon which she has conferred the attribute, ability, or power of stimulating to the discharge of its physiological function each of the several varieties of nerves in existence. That such is a fact cannot admit, as I regard it, of question. Such being the case, a nerve (or its more essential part—*viz.*, the ganglion under consideration) may be regarded as being placed, as it were, *intermediately* between two entirely distinct and separate objects, with *each* of which it is designed by Nature that that nerve or ganglion should communicate; or in other words, with *each* of which it has been placed in a certain, special, or definite relation. Between these two objects (which are physiologically disunited, except through the intervention of nerves) that nerve may be regarded as acting, as it were, as a bond of connexion. The nature of that connexion is this—namely, through the intervention of that nerve (and exclusively and alone through *its* intervention as a *normal* event) some physiological change or effect can be produced by the one upon the other of those

two objects between which that nerve has been placed. From the one (*viz.*, of the two objects referred to), that nerve *receives* such stimulation or impression as can call into operation *its own* function; to the other (*viz.*, of the two objects referred to), that nerve *communicates* such stimulation or impression as can call into operation the function of that other. Consequently, *intermediately*, as it were, or *between* those two disunited or separate objects, the *ganglionic* or (more indispensably) *essential* portion of that nerve *must* of necessity have been placed in order to admit of each of those objects holding, as it were, intercourse with that ganglion.

If, then, these two disunited or separate objects (*viz.*, those with *each* of which the ganglion in question is required to communicate) could have been so placed or positioned by Nature (*viz.*, in the general arrangement or distribution of the several tissues in man); if, I say, these two objects could have been so positioned or placed (with regard both to each other and to the ganglion which intervenes) as to admit of their coming *directly* into physiological contact, *each* with that ganglion which it is required should communicate with *both*; if, I say, such had been the arrangement adopted by Nature, *then* there is reason to suppose that there might have been no necessity for the existence of the *fibrous* portion of nerves. I shall attempt to express myself more clearly. If Nature, in her distribution (that is, relative arrangement or disposal) of the several distinct orders of organized structure which enter into the constitution of man, had *so placed* those several structures as in *all cases* to admit of the two objects under consideration, and the ganglion with which they communicate, all three occupying such position as that—1st, *one* of those objects could *directly* (that is, without the intervention of anything) produce the requisite physiological effect upon the *ganglion*; and 2nd, that the ganglion could *directly* (that is, without the intervention of anything) produce the requisite physiological effect upon the *other* of those objects (that is, upon the organized structure which the nerve or ganglion in question has to stimulate to the discharge of its function); if, I say, such *had been* the arrangement adopted by Nature, *then* there is no reason to suppose that the superaddition to that ganglion of the *fibrous* portion of a nerve would (as we now find to be the case) have been requisite. But such *has not been* the arrangement adopted by Nature; but her arrangement, as the reader is well aware, has been far otherwise. So far from *each* of the objects under consideration having been in all cases placed *directly* in physiological contact with the ganglion with which they communicate, *both* those objects are frequently placed at a *remote distance* from that ganglion (I say “frequently” so placed, for such, as we shall presently see, is not *always* the case with regard to *both* of those objects.) To connect each of those objects (which, as I have just observed, are not infrequently distantly separate), to connect, I say, each of those objects *physiologically* with the ganglionic, or (more indispensably) *essential* portion of a nerve, is the special function of the *fibrous* portion of nerves; consequently the function of that fibre *may be* (as I have already remarked) *twofold*; or in other words, a ganglion may require to have attached to it *two distinct fibres*.\*

Through the agency or instrumentality of one of those fibres, an impression (or the effects of a specific stimulus) is propagated or conveyed to the ganglionic portion of that nerve to call into operation *its* function. Through the agency or instrumentality of the other of these fibres, nervous “agency,” “influence,” “energy,” or “force” (or

the effects of its action), is propagated or conveyed from that ganglion to call into operation the function of some other structure.

The function, then, of the *ganglionic* portion of a nerve is *to develop or generate*; the function of the *fibrous* portion is *to propagate or convey*; and these two portions conjointly constitute what we understand by “a nerve.”

Every nerve may, then, *physiologically* speaking (that is, in reference to the discharge of the function of such nerve), be regarded as having of necessity *two distinct points of relation and contact*; that is, in other words, a nerve (in relation to the development or the manifestation of its function) may, in the strictest propriety of terms, be looked upon as having been essentially constructed with *two distinct points of communication*—namely, points at which one and the same nerve can communicate with two altogether distinct objects. These two distinct points of relation and contact, I would now, for a moment, for the sake of perspicuity and clearness (although, *anatomically* speaking, such expression may not, perhaps in all cases, be received, as strictly correct), these two points, I say, of relation and contact, I would now, for the purpose of making myself clearly and distinctly understood, venture to term *the two extremities* of a nerve.\* A nerve, then, may be regarded (*physiologically* speaking) as having two distinct and opposite extremities, one of which I would for perspicuity term *its recipient extremity*; the other, its extremity of *communication*. At its recipient extremity a nerve *receives* an impression communicated to itself by that nerve's own specific stimulus; with which specific stimulus the recipient extremity of that nerve is invariably placed by Nature in *direct* physiological contact. At its extremity of communication that nerve *communicates* an impression (*viz.*, the stimulus of nervous “influence” or “force”) to such organized structure as that nerve has to call to the discharge of its function; with which organized structure the extremity of communication of that nerve is invariably placed by Nature in *direct* physiological contact.

The *relative position* of the two extremities of a nerve is not constantly the same, but on the contrary, is subject to variation, and the variation found in Nature of that relative position suggests a natural division of nerves. Of this relation (*viz.*, as to the *position or locality* of what I have termed the *extremities* of nerves), it will be sufficient for the object I have at present in view, to enumerate the three following varieties.—*viz.*, 1st, the *recipient extremity* may be placed in a *peripheral or circumferential position* (*viz.*, in relation to the general frame), and the extremity of communication in an *opposite or central position*; or *vice versa*; 2nd, the *recipient extremity* may be placed in a *central position*, and the extremity of communication in a *peripheral or circumferential position*; or 3rd, *both extremities* may be placed in *one and the same position*—that is, with regard to periphery and centre. These three natural divisions of nerves (each of which is to be found in the human organization) are all those to which it will be necessary for my present purpose to direct the reader's attention. I shall now make a few observations upon each of the foregoing three natural divisions of nerves, and my observations thereon shall have relation to each of the three following considerations; *viz.*, I shall endeavour to contemplate some nerve or nerves belonging to each of the three divisions referred to—1st, in its relation to *its own* specific stimulus (that is, in its relation to the object or entity provided by Nature for calling it, in a normal or natural manner, to the discharge of its own physiological function); in a word, in its relation to the entity which *calls it* into action; 2nd, in its relation to the organized structure which it is destined to stimulate to the discharge of its function (that is, in its relation to the residual product with which that nerve has been placed in anatomic connexion); in a word, in its relation to the

\* I have used the words “may be,” “may require,” &c., in the above paragraph, inasmuch as such does not appear to be *always* the case, but a *single fibre* (*viz.*, to convey nervous influence from the ganglion to the structure to be stimulated) appears to be all that in some instances has been required; in other words, a ganglion (as we shall presently perceive to be the case) may receive an impression *directly* (that is, without the intervention of a fibre) from its own specific stimulus, or which amounts to the same thing, a ganglion has in some instances been placed in *direct* physiological contact with the stimulus which calls it into action.

\* Although such form of expression is, as I regard it, *physiologically* speaking, in all cases, strictly admissible and correct, I am aware that in some instances it does not appear to be *anatomically* applicable; such, however, does not (as it appears to me) render the above employment of it objectionable.

entity which it calls into action; and 3rd. as to the *locus* or position of the ganglionic portion of such nerve.

First, then, with regard to those nerves whose recipient extremity has been placed in a peripheral or circumferential position, and whose extremity of communication is central. Of this natural division of nerves, we have an example in what are called our nerves of sensation, including both the nerves of special and of ordinary sense. Let us, then, inquire into the *natural relations* of our nerves of sensation; let us, in other words, inquire *between what two distinct objects* have our nerves of sensation been placed, as it were, *intermediately* by Nature? Between what disunited or separate objects do these nerves act, as it were, as a bond of connexion? The answer to this question will disclose to us the two following facts—viz., 1st. the various specific stimuli provided by Nature for our various nerves of sensation; and 2nd. the organized structure or residual product with which those nerves have been placed in anatomic connexion, and which they have been destined by Nature to stimulate to the discharge of its function.

The question as to the natural relations of our nerves of sensation admits of an easy reply. Those nerves have been obviously placed by Nature in physiological relation and contact with each of the two following disunited or separate objects—viz., 1st. with those properties or qualities in external creation which we term the *sensible attributes* of the objects in the world that surrounds us; and 2nd. with that organized structure or residual product which has been specially constructed and adapted by Nature for conveying the effects thus produced (viz., by the operation of those attributes upon our nerves of sensation) to that (whatever it be) which within us is conscious. Of conveying, I say, or of communicating those effects to the conscious part of our existence or being. In other words, our nerves of sensation have been anatomically connected at their extremity of communication with that portion of the encephalon through which, as through their channel, the effects produced by surrounding creation (through their recipient extremity) upon those nerves are, as it were, presented or introduced to the mind. For the reader will bear distinctly and clearly in mind, that as there has been but one channel provided by Nature through the agency of which its food can be conveyed or introduced to the body, which channel has been termed "the alimentary canal"; so, in like manner, there has been but one channel provided by Nature through which its food (if such term be allowed), viz. impressions from external creation, can be conveyed or introduced to the mind, and that channel is what has been termed "the seat of sensation."

In the former, the two foregoing disunited or separate objects (viz., in the sensible attributes of the objects of external creation); the reader will at once recognize the specific stimuli of our nerves of sensation. At its recipient extremity (placed in a peripheral or circumferential position—viz., at the surface of our frame) each such individual nerve of sensation has been placed by Nature, in direct physiological relation and contact with some object, agency, attribute, or entity (be it what it may), in surrounding external creation (such, for example, as the colours, respectively, of what are said to produce visible, audible, oliferiferous, tangible, &c. impressions); has, I say, been placed in direct physiological relation and contact with some entity or attribute which, and which exclusively and alone, has been specially adapted by Nature for communicating to that special or individual nerve the peculiar species of stimulus which has been made indispensable essential to the calling of that special or individual nerve to the normal discharge of its function; that peculiar species of stimulus (and consequently specific), in the absence of the operation of which no other arrangement has been provided by Nature whereby it is possible (in conformance with existing arrangements) that the special nerve under consideration could, in a normal or natural manner, develop its function. In other words, the recipient extremity of each individual nerve of sensation has been placed by Nature in physiological relation

and contact with that special entity or attribute to be stimulated by which (that is, to be adapted for receiving therefrom the stimulus specially requisite for the normal disturbance of its condition of quiescent vitality); to be adapted for being stimulated, I say, by which, was the special design Nature had in view in constructing that nerve; that is, of giving to that nerve whatever is peculiar or specific in its construction.

The remote cause, then, of that change or alteration in the state or organic condition (viz., what I have termed the process of degeneration) which Nature has made it essential should be in operation in that portion of the encephalon termed "the seat of sensation" while in the act of discharging its function; that is, during "the feeling of a sensation"; the remote cause, I say, of such change or degeneration is the object or attribute in external creation which has been specially adapted by Nature for communicating the required specific impression to the recipient extremity of some nerve. The proximate cause of that change (or degeneration) is, as I conceive, the nervous influence caused thereby to be shed upon "the seat of sensation."

Where, then, we are led to inquire, does the nervous influence thus shed upon that "seat of sensation" come from? Where (that is, from what locality or position) is the nervous influence thus called into operation obtained? Where, in a word, is that nervous influence developed or generated? This brings us to the investigation of the third topic of consideration in connexion with the inquiry more directly before us—viz., as to the locus or position of the ganglionic or (more indispensably) essential portion of our nerves of sensation. The reader is, doubtless, familiar with the anatomy of the nervous system of man, and will consequently meet with but little difficulty in finding the locality of these ganglia. In the spinal nerves, for example, he will find the ganglia of the nerves of ordinary sense placed upon what is termed "the posterior root" of the spinal nerves (viz., in the intervertebral foramina, that is, located somewhat about midway between the recipient extremity and the extremity of communication of those nerves). (The general appearance of such nerves is somewhat as follows—viz., one continuous cord, somewhat about the middle of which a ganglion is placed.) The reader has but to run over in imagination the anatomy of the several nerves of special sense, upon each of which he will find, some where, a ganglion.

I have now (in conformance with the plan or arrangement proposed for the present inquiry) attempted to take a rapid and cursory, but consequently but imperfect and unsatisfactory glance at the nature of the two following relations—viz., 1st. as to the manner in which the united results of the regenerative process are related to surrounding creation; and 2nd. as to the manner in which individual results of that process are related to the one or the other. I have endeavoured, in other words, to place concisely before the reader a brief general outline or sketch of the reply to each of the two following questions—viz., 1st. how nervous tissue, cerebral matter, and muscular fibre in man, are collectively related to the world which surrounds him; and 2nd. how each of those final or ultimate results of the process of generation is individually related to the one to the other. Feeling that it would be undesirable, in connexion with the subject of present inquiry, to attempt (in accordance with my original intention) any minute inquiry into the nature of mental operations, or any detailed

The reader is doubtless aware that in speaking above of the cause of the degeneration of what is termed "the seat of sensation," I of course refer exclusively to the specific cause of that degeneration; the incidental cause of the degeneration of that structure, in common with all organized structures in creation, is (as the reader is aware) oxygen gas.

It is unnecessary for the present purpose to point out the exact position of each of those ganglia, inasmuch as that position varies with the various nerves of special sense, and its demonstration would consequently occupy, unnecessarily, much space. The reader, however, will feel no difficulty in finding out this position.

investigation into the special functions of individual portions of the brain. I shall at present merely recapitulate the foregoing observations.

It was my original intention, when commencing the publication of these papers, to have ventured to submit to the consideration and judgment of the readers of the Medical Press some observations and opinions of my own in relation to what are termed "the operations of the mind," and upon the development of mental phenomena generally. I then felt desirous of attempting, if possible, to lessen in any degree, however trivial, the extreme obscurity in which such considerations (so far as I am informed) appear to me to be at present involved; and with such motive I contemplated venturing upon a few observations and opinions upon each of the six following topics, viz., 1st, upon the formation or development of what are called ideas; 2nd, upon the deposition or storing of those ideas (when their formation or development has taken place), whereby we are enabled (by the faculty termed "memory") at some future period (and observe in the total absence of all impressions from objects in external creation) clearly and distinctly to re-produce before the mind the impressions long since communicated by objects in external creations; 3rd, upon the decomposition of ideas in the formation of what logicians call judgments; 4th, upon the comparison of judgments in the process termed reasoning; 5th, upon what are termed "inactive phenomena;" and 6th, on emotional phenomena. Upon these subjects, I say, it then occurred to me to hazard a few opinions of my own. Reflection, however, has convinced me that it would be more desirable to abandon the consideration of all such topics in the present series of papers, and that, among other reasons, from an apprehension that the investigation of such questions, in a strictly medical and chiefly practical publication, would in all probability be regarded by the great majority of its readers as inappropriate. I have consequently, upon consideration, resolved, in the present series of papers, to endeavour to confine myself, as much as possible, to the exclusive contemplation of such topics as I conceive to bear directly upon the general inquiry before us, or else to such as may appear to me to be essential to the rendering of my observations, with perspicuity, clearly and distinctly intelligible to all. It may be necessary for me here to observe, that to me it appearing to be not only desirable but important, clearly and distinctly to discriminate in the mind between nervous tissue and those organized structures through whose agency or instrumentality are developed what we term mental phenomena (from what logicians term "simple apprehension," to the most elevated intellectual developments). I have treated of these tissues throughout these observations as two distinct and separate orders of structure. It does not appear to me to be a philosophical division of structures to classify under one and the same order of tissue (viz., nervous) two structures so widely different in the nature of their physiological functions as a nerve which has simply to develop that which is called into operation during what is termed "a reflex action;" and that organized structure which has to develop the simplest conceivable mental phenomena, and, a fortiori, the loftiest intellectual operations, named "reasoning." It does not, I say, appear to me either to be a philosophical classification, or to contribute to a simplification of the science of physiology, to designate both such structures by any common appellation, such as "nervous matter," "ganglionic matter," "ganglia," &c., simply because (it may possibly be arising from the imperfection of our senses, of our instruments, or of folly; simply, I say, because we may not be enabled to recognize between these two structures any distinction in anatomic construction. Distinction in function would to me appear to be a far more legitimate source of classification (that is, ground for divisions into classes, orders, &c.) of the objects of the science of physiology, than distinction in constitution or construction. Two organized structures, apparently differing somewhat in the nature of their constitution or construction, but appearing to be one and the same with regard to the nature of their functions (say, for example, what are commonly called "the ganglionic nerves," and what we term the "nerves of voluntary motion," the fibrous portion of the former of which is gray, while that of the latter is white, consequently they differ somewhat in construction); two such structures, I say, may, as I regard it, with propriety, be classified under one and the same generic term "nerves." But two organized structures, though apparently alike in anatomic construction (such as the ganglionic portion of a nerve, and what I have termed "cerebral matter"), if mani-

That within us, which feels, and thinks, and wills (whatever it be, or whatever be its nature), may, for perspicuity and without involving hypothesis, be designated—the conscious principle of our nature or being. The reader will bear in mind that I make use of such terms (in like manner as I have already employed the like terms "nervous principle") simply to express this, viz., the unknown cause of recognized results. That principle (so long as it remains associated with what we term "material creation") can—1st, be called into operation or action; and 2nd, discharge or develop its functions, exclusively and alone, through the agency or instrumentality of certain organized structures or residual products (collectively named "cerebral matter," with which (during its connexion with physical matter or sojourn on earth) that principle has been intimately associated by Nature. The several organized structures or residual products which constitute, if I might so term it, at once the dwelling and the field for the operations of this principle (collectively named "cerebral matter") have been constructed by Nature with the following design—namely, of placing this conscious principle so in relation with surrounding creation as that—1st, it may itself (viz., that within us which is conscious) be acted upon by the objects in the world that surround it, and be thereby aroused or stimulated to the discharge of its functions; and 2nd, that it (viz., the conscious part of our nature) thus aroused to the discharge of its functions, may direct its operations in either or both of the two following channels—viz., 1st, it may react, as it were, in the direction of external creation—viz., upon those nerves which are connected with our voluntary muscles (through whose agency we are brought into relation with the objects that surround us); or 2nd, it may act upon those organized structures or residual products (viz., cerebral matter) which develop or give manifestation to what we term "intellectual," "emotional," &c., phenomena. According (as I conceive) to the specific or individual residual product (of the accumulated products "cerebral matter," upon which this conscious principle directs its operations, will there, as it appears to me, be a variation in the nature of the phenomena developed.

Now, that portion of cerebral matter (viz., the seat of sensation) through whose agency or instrumentality are developed the first class of phenomena referred to; that is, which communicates to the conscious part of our nature the impressions it receives from external creation; that portion, I say, of our encephalon has not been so constructed by Nature as to be adapted for receiving the impressions or stimuli (required for the development of its functions) directly from the objects in surrounding creation; but, on the contrary, it has been made essential (to

feels widely dissimilar in the nature of the functions they are respectively called upon to discharge, may not, as it appears to me, with propriety be classified under one and the same common appellation, such as "ganglionic matter," "ganglia," "nervous matter," or the like. It was for the purpose of attempting to keep this distinction clearly before the mind of the reader, that in the above observations I have given to all these structures whose function is to develop mental phenomena (from what is termed "simple apprehension" to the most lofty intellectual developments) the common generic appellation "cerebral matter," in contradistinction to "nervous tissue." I am not unaware that objections might possibly be urged against such term being employed for this purpose, but to this I attach, in the present instance, but little importance, inasmuch as I am at present simply desirous of convincing the reader of the propriety of adopting some distinction in terms to specify a distinction in structures which differ so widely in the nature of their physiological functions. I adopted the term "cerebral matter" simply from a reluctance, already expressed, to any attempt at inventing new terms. When first I introduced the expression "cerebral matter" into these papers, I contemplated attempting to proceed much further with an investigation into its functions than I now consider would, in this place, be desirable. To the functions of the cerebellum, and to its relations to other parts of the brain, I have not considered it desirable at present to refer, not appearing to me of necessity to bear upon the subject directly before us.

the normal discharge of its functions) that those impressions should be conveyed to that structure indirectly through the agency or intervention of what we term "nervous influence or force." Hence, a variety of nerves (constructed with an adaptation or ability, 1st, to generate, and 2nd, to propagate the requisite nervous influence or force) have been placed by Nature in direct anatomic connexion, at their extremity of communication, with the special portion of cerebral matter under consideration (viz., "the seat of sensation"); while the recipient extremity of each of those nerves has been placed in relation and contact with some object in external creation specially adapted for communicating to that nerve its requisite stimulus. The impression communicated by these nerves to what is termed "the seat of sensation," calls into operation its function, whereby the conscious principle of our being is called into action, which principle directs its operation in either or both of the two channels referred to. These, as I conceive, two distinct orders of organized structure—namely, 1st, cerebral matter, to develop or give manifestation to mental phenomena; and 2nd, several varieties of nerves (viz., adapted to the several varieties of sensible objects or attributes in creation) to stimulate that cerebral matter to the discharge of its functions; these two distinct orders, I say, of organized structure in conjunction constitute the apparatus constructed by Nature for the development of the phenomena of mind. This apparatus, complete in itself, and composed, as I regard it, of two essentially distinct parts (viz., 1st, of a system of nerves to generate and propagate nervous influence or force; and 2nd, of cerebral matter to develop phenomena altogether peculiar to itself); this apparatus, I say, complete in itself, and composed, as I regard it, of two essentially distinct parts, has been, as it were, superadded to, or superimposed upon, a nervous apparatus (complete in itself) constructed for the motor requirements of the system. I say motor requirements; meaning thereby those nerves which are employed in the production of the movements which take place in the system.

Now, the movements which take place (under the control or regulation of nerves) are of a twofold description or nature—namely, some of those movements are regulated or controlled by our will, while others are altogether free or independent of volition. The nervous apparatus constructed for the motor requirements of the system must consequently be divisible (as we find to be the case) into two distinct or separate systems—viz., what are termed voluntary and involuntary nerves. The former of these systems (viz., our voluntary nerves) is connected with cerebral matter by what we term volition; the latter (or involuntary system of nerves) is connected with cerebral matter through the agency of what are termed our emotions.

Upon the connexion of cerebral matter with our voluntary system of nerves, I shall make a few observations in my next communication.

(To be continued.)

### CASE OF OPEN FORAMEN OVALE.

By JOHN STRUTHERS, F.R.C.S., &c.

(Read before the Edinburgh Physiological Society.)

This heart presents,—1st, an open foramen ovale; 2nd, a large Eustachian valve; 3rd, contraction and hypertrophy of the right ventricle, with contraction of both its orifices.

The foramen ovale admits the little finger—i.e., is equal in size to a circular opening of the diameter of half an inch. Its valve is imperfectly developed, thick, and muscular-looking. It does not reach to the upper margin of the foramen, although its horns on each side reach higher than the opening.

The Eustachian valve is very large and loose, much more so than at any period of fetal life. It measures nearly an inch (7-8ths) from its attached to its free border; and when lifted upwards, it reaches for one-third of its depth above the upper margin of the foramen ovale. It is cribriform, especially at the right half of its attachment, and also above, near its free margin.

**Right ventricle.**—The walls are 3-16ths of an inch in thickness, whilst those of the left are from 3-16ths to 4-16ths. In addition to hypertrophy of the walls, there is likewise contraction of the cavity, which is apparently about one-half the size of the left.

**Tricuspid orifice** admits the little finger (4-8ths inch), whilst the **mitral orifice** admits the forefinger (5-8ths). **Vena cava superior** admits little finger with difficulty. **Vena cava inferior** admits forefinger easily. **Foramen ovale** admits little finger moderately, as already noticed. **Tricuspid valve** much thickened. **Corda tendinea** shorter and thicker than on left side, and **musculi papillares** large. **Mitral valve** appears healthy, except that there are a few vegetations on both its flaps, where the cords chiefly join them. **Aortic valves and orifice** natural. The orifice measures 3-8ths of an inch in diameter.

**Pulmonary orifice and valves** much contracted and altered. The semilunar valves are united together into one solid mass, with a small aperture in the centre. Seen from above, there is the appearance of a nipple, smooth and rounded, and perforated in the centre by an aperture not larger than a crow-quill, the whole somewhat resembling a cervix and os uteri. Surrounding the base of this nipple-like projection, and separated by partitions which join the central papilla, are four semilunar recesses, corresponding to the sinuses of Valsalva, and to the cavities of formerly existing semilunar valves. One of these is nearly as large as the other three together; it is left and posterior; one of the smaller is anterior; the other two are on the right side. Seen from below, the orifice appears blocked up by four irregular tubercular projections; two anterior, and two posterior; one of the posterior is large, the others are of equal size. They are firm and irregular, but covered by a serous membrane; and in between them is the small aperture which leads up through the central papilla. On pushing the probe down into the sinuses of Valsalva, it pushes out the membrane at a considerable distance below the tubercles.

The **ductus arteriosus** admits a small wire with difficulty, and was therefore practically closed. Both lungs are studded with tubercles of the size of small peas or grains of corn, on their surfaces as well as throughout their substance.

**History during life.**—A month before death, there was difficulty of breathing, the lungs appeared healthy, and the case much resembled one of disease of the mitral valve. Ten days before death, occasional blueness of the surface made its appearance, lasting only a short time, without any paroxysm of difficult breathing; and then passing off. Death occurred suddenly. The case belonged to my friend Dr. Campbell, for whom I conducted the post-mortem examination, and to whose kindness I am indebted for this use of the preparation.

**Remarks.**—A more or less open foramen ovale is well known to be the most common imperfection of the heart, but the causes of this condition are perhaps not generally understood or agreed upon. We may refer it to two causes—1, an impediment to the free passage of the blood through the right ventricle, from contraction of one of its orifices; and 2, to an imperfect development of the valve by which the foramen is usually completely closed at, or soon after, birth.

1. The connexion between contracted pulmonary orifice and open foramen ovale has been remarked by various observers. M. Louis regards it as the most common cause of the open foramen, and farther looks upon this pulmonary contraction as almost always a congenital condition. Out of 53 cases of imperfect heart quoted by Dr. Joy in the "Library of Medicine," the foramen was open in 33, the pulmonary artery contracted in 22; and it is not unlikely that in many cases the open state of the foramen ovale has been recorded, whilst the condition of the pulmonary artery and its orifice had not been carefully examined. The case I have related illustrates this connexion between open foramen ovale and contracted orifices of the right ventricle. Still the question occurs, Why should there so frequently be valvular disease and contracted orifice on the

right side in the fœtus and child, and not in the left, as in the adult. I do not think that this can be explained by the supposition that the right ventricle has, relatively to the left, more labour to perform in the fœtus than in the adult. In the fœtus, it is usually remarked as interesting to observe that the walls of the right ventricle are as strong as those of the left, or nearly so; but this I think has been overstated by some. In the fœtus between the fourth and fifth month, now before the Society, it will be observed that the left is twice the thickness of the right; and in the other fœtus I now show—at the third month—the difference is already well marked. We can see no reason then, why, during the latter two-thirds of fetal life, and in early childhood, the right ventricle should be the seat of hypertrophy and valvular contraction, and not the left. The fact of the foramen ovale being open, seems to be sufficient proof of the correctness of the view of M. Louis, that the pulmonary contraction is congenital, otherwise in the meanwhile the foramen would have become closed. Still it is not apparent why in the fœtus the pulmonary orifice should be the seat of malformation or disease more than the corresponding aperture of the left and stronger heart. The view may occur, that this contracted state of the orifices of the right ventricle and pulmonary artery, is not the cause but rather the result of the condition of open foramen ovale. This view might accord with the state of simple contraction of the pulmonary artery or its orifice, as part of the blood which should pass through them has found another channel; but it certainly will not account for diseased or malformed conditions of the right ventricle and its orifices.

I may observe that in the case I have related, it was the orifice merely which was contracted, not the artery, as, a short distance above their orifices, the measurements of the pulmonary artery and aorta were the same. Some cases have been recorded of contracted or obliterated pulmonary artery, in which the ductus arteriosus remained open so as to allow of a recurrent circulation to the lungs, but in this case the ductus arteriosus was practically closed. From this it may be inferred that the severe contraction of the pulmonary orifice had not been of very long standing, possibly not before the symptoms became aggravated, and occasional cyanosis made its appearance, about ten days before death.

2. Passing over the possibly correct view of some that the foramen ovale is occasionally again opened, or burst open, by severe falls, prolonged fits of coughing, or severe straining,—the next cause of open foramen ovale is the imperfect development of its valve.

In connexion with this, it is necessary to understand clearly the natural means by which the closure of this aperture is effected after birth. In the well-developed fetal heart, the inferior vena cava terminates so that it may be said to open into both auricles, and each opening is provided with a valve. The Eustachian valve partly guards or lies over and diminishes its opening into the right auricle; and its opening into the left auricle, which is the foramen ovale, is guarded behind by the valve of that foramen—the *valvula foraminis ovalis*. It is still a disputed question, whether the blood of the lower cava mixes with that of the upper. Now there is nothing to prevent the blood of the lower cava from coming forwards into the general cavity of the right auricle, only it must turn forwards at right angles to its previous course, around the free margin of the Eustachian valve; and that part of it does so, appears evident from the consideration that the inferior cava is larger than the foramen ovale, whilst the tricuspid orifice is as large as those of both cavæ put together. This is seen in the fœtus, between the fourth and fifth month, now on the table; and the foramen ovale becomes smaller as fetal life advances, for although it attains, as usually described, its maximum size about the sixth month, still, relatively speaking, the communication between the two auricles gradually decreases from the first appearance of the auricular septum about the ninth week. Whilst, then, that blood which does go by the foramen ovale is still entirely of the purer current, from the lower cava, it fol-

lows, as the foramen is of less size than the vein, that some of the blood of the latter, that which the foramen ovale cannot take in, will enter the right auricle and mix with the other current. This, therefore, appears to be one of four points where there must occur some mixture of the pure and the less pure currents of the fetal blood—the second is in the left auricle, where the blood which has passed through the foramen ovale is mixed with that blood which comes, whatever its quantity may be, by the well-developed pulmonary veins; the third, where the arch of the aorta and ductus arteriosus join, where it does not appear how some of the blood of the former can avoid passing down to the thoracic aorta; still, however, this is not till the vessels of the head have been filled by the purer current; and the fourth, or rather the first and chief point of mixture, is where the blood of the hepatic veins and ductus venosus is mixed with that of the vena cava inferior. A great part at least, therefore, of the blood of the lower cava passes through the foramen ovale. But to prevent this after birth its valve is provided. This valve is rather a provision for closing the aperture at birth, than for any part it has to perform before this time. Although, many years ago, it was the subject of much attention in France, it has perhaps been a little overlooked by some, partly, perhaps, for want of a distinctive name. It is the "*valvula foraminis ovalis*," and I may venture to suggest for it the term *obturator valve*, as its office is to shut up the foramen at and after birth. According to most authorities, this valve begins to be developed towards the end of the third month. It is not until the end of the second month that the septa of the ventricles and bulbus arteriosus are completed, and then an imperfect auricular septum is formed, leaving the foramen ovale at its lower part. The true or defined foramen ovale is itself, therefore, not formed or marked out until, at least, after the end of the second month. Some have found the valve, at the end of the second month (Senac and Portal, according to John Reid), and in the fœtus now before the Society, which I have ascertained to be near the end of the third month, this valve is developed so far that it rises up above the middle of the foramen, and is as high as the free edge of the large Eustachian valve, which lies in front of it. At the end of the fifth month, according to Cruveilhier, this valve is large enough to cover over completely the orifice of the foramen ovale; and this will be seen to be the case in the fœtus between the fourth and fifth month now before the Society. The valve in its lower 2-3rds grows from the sides of the foramen ovale, but, above, its horns pass upwards and outwards from the opening as far as 1-16th of an inch above it; and, when the valve is lifted or floated up, it is more than sufficient to cover over the foramen ovale.

We see then that, as early as the middle period of uterine life, this valve, or obturator membrane, is so fully formed as to be capable of shutting up the foramen completely. At birth it is floated up by the reversed current, and applied against the foramen; and becoming united or glued to it, the septum auricularum is completed.

We can understand, then, how an imperfect development of this valve will give rise to the condition of open foramen ovale, as there is no other means by which the communication between the auricles can be closed; and if in any case we find this valve so undeveloped that, on being raised, it cannot shut up the foramen ovale, we may justly consider its non-development as a sufficient reason for the foramen ovale being open.

This imperfect condition of the valve may be attributed either to its simple non-development, as the growth of this, as well as of various other parts, may be withheld without any apparent physical cause; or it may possibly be due to obstruction at the orifices of the right ventricle. Were the latter condition to exist, thus rendering impossible the closure of the foramen ovale at birth, although its valve had been well formed, analogy would lead us to expect that the valve should present a thin and reticular appearance, like an ordinary wasting Eustachian valve, rather than appear simply small and undeveloped; but were the pulmonary orifice to become malformed or contracted during

the two first months of fetal life, before the time for the development of the valve had arrived, this might possibly influence the non-development of the valve, besides causing all the other appearances which the heart presented in the case I have related to-day. However, whilst contracted pulmonary orifice is undoubtedly a frequent concomitant and, it may be, precedent, of open foramen ovale, it is at the same time by no means invariably or necessarily so. In examining cases of open foramen ovale, I would suggest that care be taken to examine especially into these two points:—1, whether there is contraction of the pulmonary or tricuspid orifices, as compared with the aortic or mitral; and 2, whether, with or without this, there is deficiency of the obturator valve, which, lying on the left aspect of the foramen ovale, should be found in its fully developed state more than sufficient, when lifted up, to shut up the aperture.

These, then, it appears to me, may be laid down as the two causes of the condition of open foramen ovale. In the one case its obturator membrane may have been fully formed, but it is kept open by the blood which cannot find a free passage through the right side of the heart; in the other case, the membrane, which should be ready to close it up, is too small, and it remains open for want of any provision to close it; and again, these two conditions may be found to coexist, as in the case I have related to-day.

Another question in connexion with open foramen ovale after birth is—Whether any mixture of the blood occurs, and, if so, to what extent, and under what circumstances? It is well known that this foramen has often been found open to a considerable extent in those in whom such a condition was not suspected during life. I mean a much larger opening than the small oblique slit which is very often found at the upper part of the fossa ovalis. Now, to understand this, let us first see how it is in the fetus. I believe it is the common idea that the foramen ovale is merely a hole from one auricle to the other, and that the right auricle drives the blood through it to the left. But it cannot be so. There is no reason to believe that the auricles do not fill and contract together as in the adult, and so also the ventricles. Now the right auricle would require to contract first, were the left filled by it through the foramen ovale, and thus at the same time the right ventricle would be filled before the left auricle had time to contract and distend the left ventricle. We must conclude that the auricles and ventricles act synchronously as in the adult.

The fact is, that the lower cava fills the left auricle just as the upper fills the right, both auricles being filled during their conjoint diastole and repose; and it may be that, after all, this is a purpose, designed by the mode of entrance of the lower cava, and by the foramen ovale as much as that the two currents should be kept separate in order that the purer blood may go to the upper half of the body. Whilst either purpose separately would have required this arrangement, both are at the same time accomplished by it.

In the fetus, then, the auricles being filled at the same time in this way, they contract; but no mixture can occur at this time, as the valve of the oval hole will not allow any blood to pass back from left to right. Previous to the third month this does not hold, as the valve is not developed; but until then it may be said that the two auricles simply form one, the lower cava opening to the left side, the upper to the right. But what I desire to demonstrate is, that when the parts are well formed, as during the two latter thirds of fetal life, there is no exchange of blood between the two auricles from the mere existence of the foramen ovale; that the right auricle does not fill the left through the foramen ovale, nor does any regurgitate through it from left to right; but the left auricle is simply filled from the lower cava, as the right chiefly is from the superior cava.

Now, it appears to me that after birth it will be very much the same, when the foramen remains more or less open. Supposing that there is no contraction of the pulmonary orifice, which certainly would occasion the employment of the foramen ovale, still it appears to me that there cannot but be some amount of passage of venous

blood into the left auricle, and this to a lesser or greater degree according as the valve is developed or not, as the lower cava still pours its stream in the direction of the aperture, through which it must partly pass and encounter and mix with the blood entering the auricle from the pulmonary veins. Still the admixture occurs during the diastole and repose of the auricles; and is not from the cavity of the right auricle, but from the inferior cava, although this can make no difference on the symptoms or to the patient.

Even in those common cases where there is a small oblique slit only, I do not see but that there must be some amount of admixture. This occurs, it is well known, as often as in one out of every five or six subjects. There is usually (from the manner in which the valve shuts up the opening at birth) at the upper part of the fossa ovalis a recess, which occasionally presents a small unobscured passage admitting a probe or even a quill. Of this I have brought a preparation now before the Society, where a common quill readily passes through a very oblique passage, and along with it is seen a corded condition in front of the oval fossa, and an extremely reticular condition of an old Eustachian valve; and there is in my museum a preparation taken from a female aged 66, in which the aperture is twice this size; also the Eustachian valve is large and strong. It is commonly remarked, that this condition can allow of no admixture on account of the obliquity of the passage. But whilst I am aware that obliquity of perforation is productive of a very perfect valvular effect, as in the case of the termination of the ureters and bile ducts, still the circumstances are reversed here. The force which shuts the oblique passage—the passive flow of the pulmonary blood into the left auricle—is not stronger than and is not so direct as, the force which tends to open it, viz., the current of the lower cava; and as the direction of this is exactly in the direction of the slit, it seems to me that there cannot but be, during each diastole, a small quantity of venous blood sent into the left auricle. This, however, can be only to a very trifling extent, and would not, perhaps, be worthy of notice, were it not for the sake of fully reasoning out the effect of the various conditions of open foramen ovale. *Monthly Journ. of Med. Soc.*

## TWO CASES OF VITILIGOIDEA

By W. FOSTER, Esq., Huntingdon.

About twelve years ago I saw a young lady with a curious affection of the skin of the neck, traversing the left side diagonally from the ear towards the sternum, about one inch in width. At first sight it appeared as the scar of a burn, or skin removed from some superficial cause, not unlike a prolonged scar from the pustule of vaccination, but at the lower part the skin was elevated for a short distance, smooth, and of a colour something like a permanent wheal of urticaria; it seems that it spread by this elevation, which was succeeded by the scar-like appearance; there was no pain or uneasiness, the general health good. The appearance was anything but prepossessing, but as no indication of treatment presented itself, the case passed away with the impression on my mind that I knew nothing about it. I saw the young lady the other day, there is a very slight elevation just above the collar bone, and the scar-like appearance is much more superficial and has now nothing more than a dirty appearance.

I saw no other case until last autumn, when a young gentleman, just about to enter Oxford University, showed me what I recognized as the same disease. It appeared in his case after suppressed perspiration, as he supposed; it showed itself just above the left eyebrow on the forehead in one or more patches. I recommended him to try collodion and live well. I could not give him the name of the disease, nor say more about the treatment. I heard from him soon after, when he stated the same affection had all at once darted up his head for about an inch and a half in length, and one in width, entirely destroying the hair at the roots. He applied the collodion assiduously, took more animal food, and a few weeks since I saw him, the

disease was evidently stayed on the head (but the hair had not grown in the least), also on the forehead it was healed, but just on the eyebrow it was not gone. He complained of a sense of stiffness over the parts affected, and expressed himself very anxious as to the results. Very soon after this latter case presented itself, I found this disease described by Drs. Addison and Gull in Guy's Hospital Reports, vol. vii., p. 2, under the name of "Vitiligoidea."—*Prov. Jr.*

#### REVIEWS AND NOTICES OF BOOKS.

**ARTICLES ON REFORM IN PRIVATE LUNATIC ASYLUMS.** By HENRY MONRO, M.B. Oxon, &c., &c. 8vo. pp. 110. London, 1852.

THIS book is a republication of several "articles on improving the condition of the insane," which have appeared, from time to time, in the *Medical Gazette*, the *Lancet*, or the *Psychological Journal*, and contains, perhaps for this reason, such frequent iterations of the same views with reference to insanity, that we cannot avoid remarking, that the work might have been easily recast and reduced to half its present size with advantage. The principal objects of the reform contemplated by the author, are stated to be—"to make the commissioners and other public inspectors as responsible as possible for the conduct of private lunatic asylums; to remove all civil responsibilities from medical proprietors as much as may be; and to leave them, what is quite sufficient alone, the medical care and the charge of carrying out the details of the economy of the house." Those objects, which are considered by Dr. Monro absolutely indispensable, as well for the welfare and protection of the insane in private asylums as for the security and comfort of medical proprietors, could, in his opinion, be readily accomplished through the agency of more frequent visitation; in other words, by such an increase in the number of inspectors as would enable them to visit this class of asylums every month or three weeks, or oftener if necessary, instead of every quarter of a year as at present. The responsibility which it is proposed in this way to transfer from the medical proprietor to the inspector, is said to be chiefly that which arises in reference to the detention or discharge of a partially insane person who has been legally sent to an asylum, or of a convalescent patient about whose continued residence there is much cause of doubt; and the principal reasons adduced to show the necessity of the proposed change may be briefly stated to be—in the first place, that the commissioners being a disinterested body will be a fairer tribunal for the decision of such questions than the proprietor who has an interest in the detention of the patient; secondly, that the prejudice on this subject existing in the public mind (in England) is so strong that a proprietor has no chance of a fair hearing in a court of justice when a question of this nature comes to be investigated; and lastly, that there is, under these circumstances, something so "terrible" and intolerable to a refined and sensitive mind in the contemplation of the consequences of such responsibility, that it is only persons who have become callous through the influence of certain processes that are able to endure its pressure. It may be well, however, to place before the reader a few extracts from the work itself with reference to this subject, which may enable him to form some idea of the author's style and of the tone and spirit in which the book is written:—

"I aim at this end (the transference of responsibility to the inspectors), first, from the conviction that the public and in consequence their representatives are, and must be, the most unbiassed judges in many matters of great importance connected with the welfare of the insane; second, from the conviction that the public have proved themselves to be the most trustworthy depositories of this responsibility; third, from the conviction that little short of this can render the position of any officer of a private asylum, who has a sensitive regard for his character, comfortable, in the present day, when the public are naturally so suspicious of the private system.

I will, in a few words, state my reasons for these conclu-

sions.—First, as to the fact that the public are the most unbiassed judges, there can be no doubt, for they, and they alone, can have no private interest either in the detention or release of a patient. This consideration must be satisfactory to all; and one of the best results of this belief is, that the appeal to the commissioners has been a source of comfort to many patients before they have become acquainted with the good intentions of those they are placed with. Second, that the public has proved itself to be the surest defence to the insane, is a matter so conspicuous and significant, that it has led me to consider the sound sense and good feeling of the same public the best antidote for the morbid sense of the insane, and a refuge more to be depended upon than the care of either relatives or medical men. Experience of the past has declared this truth in a manner not to be mistaken; common sense shows us the reasons for this fact; and if such is the case, humanity demands that their voice should be attended to. For example, experience has proved to us that the care and affection of friends, with good intentions, were not in former times equal to the task of ensuring the best treatment to their suffering relatives; and common sense tells us that this deficiency was occasioned, partly by a blind trust in others and a belief that nothing could be done; and partly, by such morbid fears and false shame as caused persons so closely allied to the sufferers to stop their ears. In these cases (which I am thankful to say, are becoming daily more rare under the influence of greater enlightenment of mind), sympathy seemed to have reached its boundary, and self-protection to urge flight from a disease which shocks the feelings; and thus, too often, even tender minds endeavoured to become callous at almost any hazard. On the other hand, general philanthropy proved itself able and willing to stand the shock which the more sensitive feelings and the selfish fears of friends quailed before. The public sympathy resembled in this respect a rock in the ocean, which can offer a firm hold to him who is sinking beneath the waves; while private affection exhibited the helplessness of a companion a little stronger than his fellow, who refuses to reach out his hand lest he should be dragged into the abyss which awaits one less happy than himself. Again, experience of the past, and common sense, have declared that the various officers of asylums, allowing them to be humane and honourable gentlemen, are unfit to have the sole charge of the insane without aid or observation. Thirdly, but the motive which presses most cogently upon me, in urging the removal of the civil responsibility, incurred by detaining a patient, from the officials of an asylum to the commissioners, is, that this responsibility is on certain occasions intolerable to the former if they have not become inured to it by a process of habits and associations which it would be well for all to avoid, but which capricious fashion sometimes allows even in the pursuit of an honourable profession. As matters are at present, I believe that many men of refined feelings would refuse to undertake the proprietorship of private asylums, unless the circumstances of family connexion, &c., almost compelled them into this course. There is something so terrible to a sensitive mind in the possibility of his motives being misinterpreted, and his actions misjudged—and that, especially, in a case where all the world is inclined to suspect him, and where his less conscientious colleagues often deserve suspicion—that no wonder he withholds his steps before he enters upon ground which has so much the nature of a quicksand; and thus the event is, that those who are really best suited to this anxious and responsible work are excluded. On the other hand, could he feel that he had a competent superior to rely upon, for freeing him from aspersion, and assisting him in difficulties, he would no doubt feel the ground sufficiently secure to invite him."

"With respect to the secondary advantages which it is supposed would result from the transference of all responsibility to the inspector, it is scarcely necessary to do more than enumerate them.

Thus, in the first place, it is said—"Frequent visits are necessary to free the minds of patients of injurious anxiety." The reason assigned being, "that it frequently happens that an insane person is clear-headed enough to know that a private gain is obtained by the proprietor out of his residence in the asylum, and cannot be persuaded that justice will be done to him, and that he will be released soon, his discharge can be permitted with any propriety."

Second—"Frequent visits are necessary to free the mind of the proprietor in doubtful matters of discharge." It is obvious

that if Dr. Monro's plan of reform were adopted, no difficulty of this kind could arise to the proprietor, whose mind would be left perfectly free and easy in reference to all such matters; but we have quoted the passage, partly to exhibit the vague and unsettled character of the author's views, and partly to exemplify by another quotation his mode of treating the subject. Thus, the propriety of discharging or detaining a convalescent patient being at times a matter of some doubt, "the proprietor (he writes) is in a dilemma, and can hardly help feeling biassed one way or the other, for the points of the argument before him are these:—I doubt whether the patient should remain; I know that it is for my own advantage that he should remain (these two facts must almost of necessity arise before his mind—it is useless to pretend that the second is wholly forgotten). But the third point is very differently settled by different minds; for the sensitively refined mind says, at this juncture, 'he shall leave me;' while the less refined man says, 'I will keep him.' Both verdicts are biassed: the one dreads self-interest too much, the other dreads it too little. In such a case as this, then, the arrival of the commissioners is a boon," &c. &c.

Third—"Frequent visits are wanted to settle matters of unavoidable disagreement between patients and their ordinary superintendents and advisers;" such as differences between the doctor and his insane patient, as to "kindness of treatment, the degree of liberty permissible, and other matters of daily conduct."

Fourth—"Frequent visits will afford a reference to a disinterested tribunal a short time after a patient's confinement; and fifth, will assist to disarm that morbid suspiciousness to which most patients are prone."

And lastly—"Frequent visitation is necessary to free the minds of the commissioners of those inaccuracies of judgment which rare visitation engenders; while they would, in the same way, be enabled to supply the public with such complete reports on private asylums as would furnish the friends of the insane with satisfactory evidence of their comparative value."

We have already devoted more space to this book, and given a more extended analysis of its contents, than many of our readers will probably think it deserves; but it seems to us that any work professing for its object an improvement of the condition of that unhappy class of persons who must of necessity be so much committed to the care of strangers, ought to receive an attentive consideration from the profession. In offering some few remarks, which we deem it our duty to make on it, we are anxious at the outset to state, that we could on many occasions agree with the author if we found him agreeing with himself; but this is very far indeed from being the case. Thus, though he asserts again and again that the principal object of his labours is to have the responsibility which attaches to the management of a private asylum transferred from the proprietor to the inspector, the whole tenor of his reasoning or his reflections leads to the conclusion that every advantage he desiderates for the insane would be obtained by frequent visitation alone, without any such transference of responsibility. These contradictory views (and no views can be more opposite in principle) seem to be continually floating in his mind, and clash in every page of the book. We have no objection to frequent, systematic, and strict inspection, as long as it is restricted to its proper objects; and if, as Dr. Monro asserts, a stated quarterly visit to a private asylum constitutes the whole duty in that respect of the Commissioners of Lunacy, we agree with him in thinking it is insufficient, and may, in some cases, tend rather to foster than reform abuses. We think also that his efforts would have been deserving of much praise if, under such circumstances, he had put clearly before the public the necessity and advantages of more frequent communication between proprietors and inspectors in a calm and sober manner, eschewing the flowers of rhetoric and common-place declamation, which only encumber and obscure his views. At the

same time we must add that we are far from adopting the rather extravagant estimate formed by the author of the value of inspection as a safeguard for the insane. Inspectors are human as well as proprietors—subject to the same weaknesses and faults, and Dr. Monro has not to learn that there are many failings and defects, besides the blindest selfishness on the one hand, or an indecision of character approaching imbecility on the other, which may incapacitate a man for the proper discharge of duties of this nature. The inspector, as well as the proprietor, may be cold and callous; or he may be sensitive and timid; or he may be ignorant or inexperienced; or he may be a mere routinist. But even though he be none of these, and be, on the contrary, a person of ability and experience, well qualified to discharge such duties, there are many circumstances connected with the welfare of the insane—their daily, hourly care and treatment—which he can only imperfectly appreciate. We cannot, therefore, but smile at the proposal of Dr. Monro (who is himself, we infer, a proprietor) to establish in every asylum a Court of Appeal, under the presidency of the inspector, in which the insane patient and the doctor could appear as plaintiff and defendant, and, enjoying the benefit of the recent statute, cross-examine each other as to the measure of liberty permitted, the degree of kindness exhibited, &c. &c.

With respect to the advantages anticipated by the author from his favourite hobby—the transference of responsibility—they are altogether visionary. He appears to have no clear conception of the separate and distinct nature of the duties of the medical attendant and inspector. In the cases supposed, the medical attendant alone can have had the opportunities for acquiring such an intimate knowledge of the character of the mental malady as would justify an opinion that the patient may with propriety be discharged or detained. If the inspector were to visit every day, instead of every month, he must still be in an unfavourable position, as compared with the medical attendant, for coming to a positive decision in an obscure and doubtful case of this nature. In such circumstances, the inspector could not with safety incur the responsibility unless he had the sanction and concurrence of the medical attendant; and therefore the result, as far as the insane patient is concerned, would be practically the same in either case—his detention or discharge would mainly depend on the opinion and views of the medical proprietor. The proposed change would, therefore, have the effect of removing the responsibility from the persons upon whom it justly and properly devolves, without affording any additional security or advantage to the insane; and instead of acting as a corrective of the malpractices of mercenary proprietors, it would rather tend to encourage them; for however selfish and mean the proprietor of an asylum may be supposed to be, he cannot be altogether indifferent to the consequences of the responsibility that attaches to his acts, and to place this responsibility upon another person, who could scarcely act without his concurrence, would be only enabling him to indulge his trading propensities with less apprehension and restraint. Under the present system, if the proprietor be embarrassed as to what course he should take in a doubtful case, he can avail himself of the assistance and advice of the inspector, which is all he has a right to expect. But Dr. Monro feels also that it would be a great comfort to the refined and sensitive class of proprietors if they were relieved from the pressure of this responsibility, which is "intolerable" to them. We have no doubt it would be so, not only to them, but, as we have said, to the selfish proprietor also. We cannot, however, agree with him in thinking this a good reason for conceding to the proprietor of a private lunatic asylum what no man in society should expect—immunity from the responsibility that attaches to the discharge of his professional duties. If a medical proprietor be so refined and sensitive about his character as to shrink from the performance of his duty to his patients, he is unfit to have the care

or management of the insane; and his incapacity in this respect will be found equally injurious to them whether the responsibility of discharging or detaining a patient falls on himself or on some other person.

We cannot conclude without remarking, and we do so with regret, that Dr. Monro appears to have formed a very low estimate of the intelligence, the morality, or even the honesty of the members of his own profession, and not to have taken into account the many counteracting motives to a sordid, unreasoning selfishness which influence a medical man in the discharge of his professional duty. We are at a loss to know amongst what class of practitioners in England he has found grounds for this opinion; but if the statements or insinuations scattered through this book against medical proprietors be true, it would be better at once to abolish such establishments than attempt an inefficient and impracticable reform, such as he proposes. With respect to this part of the subject, we leave the proprietors of English asylums to defend themselves, merely expressing a conjecture that the evils complained of are for the most part imaginary, or grossly exaggerated. We should not, however, omit to mention that the ultimate object of the author's reform seems to be the extinction of this class of asylums. He nowhere, indeed, distinctly states this, and, on the contrary, has introduced a *saving* section "on the peculiar advantages of private asylums;" his convictions on this subject being, he thinks, entitled to more weight from the circumstance that he began his professional life with a strong prejudice against asylums. When we come to examine this section, however, we find it to be merely a statement of the advantages of an asylum over "a private house or the domestic circle" for the treatment of insanity; while an entire article is devoted to the consideration of a plan for the "establishment of public asylums for the middle classes," which are to be managed by a committee of subscribers with a resident medical officer; and in the Introduction to the book we find "that in the provinces an asylum of this nature has already been established on a large scale, and that schemes of a similar description are receiving much support in other quarters." It would be premature at present, with the imperfect information we have before us, to offer any opinion as to the probable results of these schemes on the insane and their medical attendants.

#### MEDICAL TRIALS.

##### NISI PRIUS COURT, NEWCASTLE.

(Before Lord Chief Justice CAMPBELL.)

Smith v. Lynch.

THIS was an action for compensation for damages alleged to have been sustained through want of care and skill on the part of the defendant, who is a surgeon in practice at Cowpen.

It appeared that James Smith, a youth about 13, the son of the plaintiff, who is a pitman, in the early part of December last accidentally fell from a limekiln, and sustained a compound fracture of the thigh-bone. On being taken home, Mr. Lynch, the defendant, was sent for, who set the broken bone, and applied splints in the usual way. A short time afterwards, the youth had a succession of fits, and the bones were displaced. The operation of re-setting was performed, but the case, which did not appear to present any formidable difficulty in the first instance, in a short time assumed a more serious aspect. Mr. Lynch attended his patient daily, and also obtained the assistance and coöperation of Mr. Cockburn, another medical practitioner in the locality. The mother and nurse of the youth, however, seem to have become alarmed at the symptoms presented, and discharged Mr. Lynch from attendance, and called in Mr. Mann and Mr. Ward, who, on examination, decided that amputation was necessary in order to save the life of the patient. Before operating, however, they deemed it prudent to confer with Mr. Fife of Newcastle, whose professional skill and scientific knowledge,

the judge remarked on sending the case to the jury, would seem to be hereditary, and whose experience enabled him to decide in the most difficult cases. Under Mr. Fife's direction, amputation was performed, and then it was discovered that the part of the bone between the fractures had ceased to possess vitality, and, therefore, never would have united. These several parties were examined on behalf of the plaintiff, the examination being directed to show that the splints were not such as ought to have been applied, and that the treatment of the patient from the first was improper, whereby amputation was rendered necessary; but on all these points the evidence failed to support the case, it being admitted, on cross-examination of the witnesses, that the splints were similar to those used in all the great hospitals of the kingdom, and that it was the duty of the surgeon to endeavour, if possible, to preserve the limb, and only resort to amputation when there appeared no other way of saving the life of the patient.

The learned JUDGE, on hearing the evidence of the medical witnesses, remarked that in his opinion the plaintiff had failed to make out his case, for that instead of proving that there had been negligence and want of skill on the part of the defendant, he proved the contrary. He left that, however, to the consideration of the jury, and remarked that if they wished to hear the counsel for the defendant, they might do so, but, for his own part, he thought that quite unnecessary.

The jury, after laying their heads together, determined upon hearing the counsel for the defendant; after which,

His LORDSHIP endeavoured still further to elucidate the case by a luminous though brief address.

The jury then, without retiring, returned a verdict for the defendant.

#### PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

##### MEDICAL REFORM.

DR. ROBERTSON said he had been called upon to move a resolution relating to the Medical Reform Bill. The subject had been before the notice of the profession for a number of years, and they had had frequent opportunities of discussing it. He might observe that Mr. G. Hastings (son of Sir Charles), barrister, who had been concerned in the drawing up and preparation of the bill about to be submitted to parliament respecting it, was in attendance to explain its leading provisions. The resolution was as follows:—That this Association consider that the Draft Bill for Medical Reform, which has been prepared by the Central Council, embodies the principles uniformly advocated by the Association, and that the bill be referred to a committee, who are hereby empowered to make such alterations and modifications in the bill as to them may appear expedient, and also to negotiate with the Home Secretary, and with the medical corporations, with a view that such bill, on the earliest opportunity, be presented to parliament, in order to its passing into a law.

MR. P. CARTWRIGHT, in seconding the motion, said, it was important that a committee should set to work actively to carry out the Draft Bill emanating from the central council; it was the more necessary as there was reason to fear that the apathy of the profession on this long debated question was so great, that when all differences were nearly adjusted, the final and crowning measure of the whole would be lost for want of energy. The Draft Bill (if not a perfect measure) had given much more universal satisfaction to the profession at large than any other measure submitted to it. It was unnecessary for him (Mr. Cartwright) to enter into details of the construction of the bill, as that would be much more ably done by a talented barrister (Mr. George Hastings), who would fully explain the provisions of the bill to the meeting. The construction of the bill was simple, not interfering with any strictly professional corporations, and appointing such penalties only as were necessary to correct irregular practice. The bill was based on the adoption of the two new charters of the Colleges of Physicians and Surgeons, which were framed in a liberal spirit,

and the latter of which has already come into operation, and tended much to heal those disputes which had existed between the College of Surgeons and their members (applause). The governing body (in the present bill) was to be formed by one-third of its members being appointed from the College of Physicians; one-third from the College of Surgeons; and one-third independently selected from the bulk of general practitioners by the Secretary of State; the council would also receive weight and dignity from the addition of the Regius Professors of Oxford and Cambridge, and from the Presidents of the Colleges of Physicians and Surgeons. It was his firm opinion that a council so selected, from the *élite* of the profession would carefully watch over the interests of the general practitioner, and would be found of much greater utility, more effective, and more agreeable to the profession, than any third incorporation. Mr. Cartwright would here appeal to those gentlemen who had favoured the proposed third incorporation? As it was now clearly impossible to carry out the institution of a third incorporation, he suggested that the appointments of such an independent medical council as the bill provided for, would form a neutral ground on which the members of the Institute of General Practitioners could unite with the promoters of this bill, and provide effectually for what they were all deeply interested in—the improvement of the status of that hardworking and deserving class, the general practitioners of the country; he hoped the appeal he now made would end in some of the Institute gentlemen being now appointed on the committee. The advantage of this would be, that if by mutual concessions an understanding could be come to, they could approach the Colleges of Physicians and Surgeons as one body, united to obtain a bill for the general benefit of the profession. It was already known that the College of Physicians approved of the measure; he hoped the College of Surgeons would listen favourably to their requirements; and such unanimity on all sides would greatly enhance the favourable opinion which the Home Secretary was disposed to entertain of the measure. In fact it had been stated, that if it could be presented to Mr. Walpole under such circumstances, it would be adopted as a government measure. He would urge the committee to push forward to such a consummation, and in the hope that ere long this long-anticipated and most important measure would be honourably and satisfactorily arranged by legislative enactment, he would conclude by seconding the nomination of the committee proposed by Dr. Robertson to carry out the proposed Draft Bill of the Central Council (applause).

Mr. G. Hastings (barrister) then rose, and at considerable length explained the steps he had taken in the preparation of this measure, under the direction of the committee of the association. He observed that it was at first desired to include within the scope of its provisions Scotland and Ireland, but from the difficulties ascertained to exist, it had been deemed advisable to confine its action to England and Wales, as reciprocity of practice could only be secured by uniformity of education. It was his belief that had Sir G. Grey remained in office, so impressed was that gentleman with the importance of the subject, a measure would have been passed by the late government which would have proved acceptable to the profession generally; but the change of administration had prevented his doing so, and singularly unfortunate was it that such change occurred only a day before Sir G. Grey would have taken up the bill. After the formation of the present ministry, he (Mr. Hastings) had an interview with Mr. Secretary Walpole, to whom (having the honour of a personal acquaintance) he explained his views more fully probably than under other circumstances he could have done, and Mr. Walpole assured him he would give the matter his best consideration, and that if a bill should be laid before him which should have the support of the profession generally, he should feel it his duty to bring it before parliament; he (Mr. H.) consequently thought that they might expect ample justice at the hands of the Home Secretary (applause). He had in the course of his proceedings endeavoured to ascertain the feeling of the House of Commons on the subject,

and with that view had asked the opinion of several influential members, the result of such inquiry being the raising of a belief in his own mind that the members of that house were heartily sick and tired of medical reform, as there had been already a number of bills before them relating thereto, and it had in consequence become very distasteful to them. Such being the case, he was induced to think, that if a bill meeting the views of the general body of the profession were submitted, the house would gladly pass it, in order to get rid of the subject and its (to them) attendant annoyance (applause). After having given a short description of the principal provisions, he said, in drawing the draft of the bill, it had been his earnest study to meet the views and carry out the wishes of the great body of the medical profession throughout England; and it was his belief, that if the association failed in the endeavour to carry out medical reform, no other single body would be able to take the matter up, and it must be allowed to drop; the consciousness of this ought therefore to incite them to a continued, vigorous, and united action. Mr. Hastings gave down much applauded.)

Mr. WALLACE expressed his dislike of the manner in which the representative council was to be constituted under the proposed bill, and which he believed would not satisfy the profession, who required the representative principle to be fully carried out. He had stated this objection when the draft of the bill was under discussion by the committee, and he hoped that the part relating to the constitution of the council would be struck out.

A MEMBER said that while two medical colleges had been spoken of as having been consulted (the College of Surgeons and the College of Physicians), no mention has been made of a third and no less important one—the Apothecaries' Company, to whom they were so much indebted. He thought that, with respect to the council, the selection ought to be made one-half from the general practitioners; and also that in the promotion of the bill, the opinion of the Society of Apothecaries should be taken, and their support solicited.

Mr. STEDMAN, observing that the meeting was under obligations to the legal gentleman who had so ably addressed them, said the gentleman who had last spoken had expressed his regret that the Society of Apothecaries had not been consulted; he, however, had to mention that another equally important institution had been passed by the Institute of Medicine and Surgery. As a member of the council of that institution, appointed by 4000 members, he could not allow the omission to pass without noticing it.

Mr. G. Hastings said it was but right he should state, that when drawing up the draft of the first medical bill, he wrote, at the same time forwarding a copy, to the Society of Apothecaries, as well as to the Colleges of Physicians and Surgeons, stating that he and the committee were anxious to have their opinion in writing, or if they would favour him with a personal interview, he would explain any portions they might wish. The Apothecaries' Company took no notice whatever of his letter; and when the second draft was drawn, he did not think it worth while to trouble them with it. As to the Institute of Medicine and Surgery, a similar course was taken in the first instance, which resulted in their giving notice of opposition to the bill; and no application had been made in the second instance.

Mr. BOWLING, of Hanmersmith, regretted that in the bill there was no provision made for examinations in midwifery. He thought there were more lives unnecessarily lost in that branch of the profession than in any other. Some stringent statutory regulations were required to ensure to the public proper obstetric education.

The Rev. Mr. BELL said, that though the practice of medicine was no longer his occupation, and though he had assumed a still more sacred calling, yet he was proud to continue to be a member of this association, and had always much pleasure in participating with his medical brethren in the advantages of these annual meetings (applause). Many years ago he had advocated changes not very different from those which were now so likely to be harmoniously carried out. He did not, however, like to trust all the

details to any committee, and he would wish to add to the motion a clause directing the proposed committee to convene a special meeting of the association to consider their amended edition of the bill.

After some debate, it was at last agreed (on the suggestion of Sir C. Hastings) that the committee should be instructed to communicate their amended bill to the central council, by whom, if the alterations involved great changes, a special meeting of the association was to be called. This arrangement gave general satisfaction, and terminated a discussion which at first seemed likely to occupy a long time.

Mr. Lonn, of Hampstead, eloquently insisted upon the claims which general practitioners had upon society: their position was not an inferior one, inferiority was the result only of misconduct and ignorance, and these might as easily degrade the pure physician and the pure surgeon as the general practitioner. He feared the representative system had been too much lost sight of in the bill, but if a good committee were appointed, he pledged himself to be contented with what they did, even though he felt that the bill might not give all that was required by the profession.

## MEDICAL PRESS.

DUBLIN, WEDNESDAY, AUGUST 18, 1852.

## MEDICAL REPRESENTATIVES IN PARLIAMENT.

We do not now for the first time agitate this question. Ten years ago or more we mooted the point, and from time to time alluded to it as one of the means by which the Medical Institutions were to be rescued from the hands of diploma jobbers and rapacious traders in academic honours. Our London contemporary, too, occasionally devoted such a measure, and as he now resumes the subject we give place to him, with the hope that his arguments may convince our readers that we have not been mistaken in our views or too sanguine in our hopes respecting the matter.

Looking back on the many years that have passed since medical reform became one of the requirements of the profession, there is nothing that affords us more inexpressible pleasure than the fact that it was our good fortune to obtain a hearing before a parliamentary committee for a few of those general practitioners who entertained the views on medical reform which we have unceasingly advocated. Those views were at that time at discount, and supported but by a comparatively small number, yet the proposals which were put forward were not only heard, but by order of the government its projectors were heard at a conference with the College of Physicians and Surgeons, and the result was that each party was leaving its own and making such an adjustment as they thought would answer for themselves. *Parliamentary Evidence.*

But, alas! alter visum est, the opinions of that small minority have triumphed. A remodelling of the charter of the College of Surgeons (strenuously declared impossible) has been effected, and the excuse for a new College of General Practitioners no longer exists. We had from us to refuse to the gentlemen of the Institute an acknowledgment that they were driven by aggravated grievances to demand a College of General Practitioners. We admit and believe it was only as a means to an end, and not for personal aggrandizement that a great majority of its active advocates sought it, but we always lamented that they should have allowed themselves to be withdrawn from the legitimate vindication of their rights, and the redress of their wrongs, in reforming the charter of the College of Surgeons, to try a dangerous experiment in creating a new institution for the profession which had experienced annoyances and heartburnings enough from the corporate powers already in existence. Since the deputation of Associated Surgeons from the provinces, which waited upon Sir George Grey in May, 1850, together with a deputation from the Provincial Medical and Surgical Association, the latter body has taken a distinguished lead a medical reform; and at their late important

meeting at Oxford the subject was brought prominently forward by that estimable veteran physician, Dr. Robertson of Northampton, in proposing the appointment of a committee for carrying out the draft bill which has been prepared under the auspices of the association for a reorganization of our profession. An extended report of the debate that ensued (see page 107, *MEDICAL PRESS*) we published in our last number, and for an analysis of the bill we must refer to the able speech of Mr. Hastings, the barrister, and to the bill itself. The bill commends itself to our notice by its simplicity and practical application. It is based on the great of new charters to the Colleges of Physicians and Surgeons. Every man who shall hereafter practise medicine and surgery must give satisfactory evidence to the State that he is qualified for the duty: one similar examination, or series of examinations, is provided for all in the first instance. Thus all will enter by one common portal; no other titles will be recognized but those which immemorial custom has sanctioned; all will be controlled under the two heads of "Physicians" and "Surgeons," and the fee that every member will pay for his enrolment and legalization (as a qualified practitioner) will become an annual contribution to a provident fund for the support and maintenance of those who, through the inscrutable dispensation of Providence, may chance to suffer sickness and sorrow, or cruel penury—a liability common to all, however bright their prospects in early life and however irreproachable their conduct. Every one who attended the splendid annual meeting must have been gratified to hear Mr. Hastings state that however much the bill had been commended by many who had written to him, by far the greatest number of anonymous had fallen to the share of the registration and provident clause. If this draft bill of the association falls short of perfection, and does not embrace all and everything we have anticipated, we nevertheless pronounce it to be a just, fair, and practical measure, eminently calculated to improve the education and exalt the status of the general practitioner. If the representative system, in the formation of the medical council is not on that broad scale that some might desire, but to which insuperable obstacles are opposed, let it not be forgotten that it is formed from colleges having new charters, in which the said system fully exists, and by selection of the Secretary of State of a certain portion from the general practitioners themselves, to whom other honorary or *ex-officio* members are added. We are inclined to concur in the judicious observations that fell from Mr. Cartwright in seconding the proposal for a committee on the draft bill. That a council so selected from the *élite* of the profession would carefully watch over the interests of the general practitioner, and would be found of much greater ability, more effective, and more agreeable to the profession than any third incorporation such as was proposed. We might add, that the construction of this council is the first initiatory step to amalgamate all classes into one brotherhood; and whilst it interferes in no way with those titles and distinctions which long usage has made familiar, and which will exist as long as the world exists, it draws all of us closer together in the bonds of good fellowship and community of interest, and melts and blends our common profession. It would exceed our limits to analyse the whole of this debate. We shall again recur to it, and more particularly to the important feature—the conciliatory appeal made to those gentlemen who have hitherto advocated a separate incorporation of the general practitioners. *Lancet.*

In all this there is nothing which any man can call unreasonable. Why should not the Physicians and Surgeons of Ireland have a representative of their own choice as well as the Graduates of Trinity College, an heterogeneous constituency having no common interest or common object?

There cannot be less than three or four thousand Physicians and Surgeons in Ireland with great interests at stake, none of them having representatives even in the Colleges from whence they derive their qualifications except about five hundred Fellows of the College of Surgeons of Ireland.

Why should this state of things be permitted? We complain not of the allowance of two representatives to the very limited constituency of Trinity College, preposterous as the privilege is to a body of men who are not allowed an

single representative on the governing board of their own body; we wish they had as many more, but we claim for others, as well if not much better entitled, similar advantages. At the moment we write a state of affairs has arisen which nothing but the most searching parliamentary scrutiny can fathom, or the most fearless discussion expose; and such parliamentary inquiry can be effected by some clever member only, who shall have been properly instructed as to cabals and intrigues, which now threaten to bring the public service into discredit, as well as to lower the medical profession in public estimation.

#### MEDICAL LIFE IN LONDON.

London, August 7, 1852.

In alluding to the practice of medicine and surgery in England, and those pure fountain-heads from which the refreshing springs of practical medicine should flow—the Royal Colleges of Surgeons and Physicians—we would not wish to be understood as attacking any person or court of examiners, but a system rotten at the core; a system, in the case of the College of Surgeons, which ignores the A B C of physic, leaving it to the utterly uneducated prescribing chemists, and, compared to the College of Surgeons in Ireland, sending out swarms of most indifferent surgeons; a system more mournful still in the case of the College of Physicians, which keeps its double-shotted batteries for the real legitimate M.D., while every shade and variety of quackery is not only countenanced, but in many instances coquetted with and fostered, the so-called chemists doing, meanwhile, the real prescribing practice.

It was Midas, wasn't it, that did such miracles with gold. We have seen lately wonders quite as great. Little petty chemists, 50 years old, turned with a Harlequin touch into surgeons; and one such member with blazing blue bottles transmigrated into a fellow of the college. Myriads of poor fellows it would be a mercy to make bootmakers, going out as surgeons in emigrant ships; and other men, really well educated, also fitting themselves for their southern expedition. Medicine, meanwhile, in London is allowed to take its own way; and, as we mentioned too often, the chief practice is confined to the chemists and quacks—no protection whatever is given the man with the diploma. There may be as many poachers on the preserves of the college as possible. There may be as much necessity for active vigorous measures to keep the commonwealth of legitimate medicine in good condition, but like the luckless surgeon Saneho Panza met at Barataria, the college knows no cure for such distempers—as it never tried.

In the societies and foreign journals something novel occasionally turns up. If we will leave the colleges to the drowsy porters and water carts, perhaps we may turn to something new. In matters of every day interest, perhaps I may mention a paper that has just created no small amount of conversation among the more "grumpy" members of the profession (there's a word for you not in Entick or Johnson), that of Tyler Smith on the Pathology of Leucorrhœa, based upon the microscopical anatomy of the os and cervix uteri. Granting that from the time of Swift and Gulliver, there are always men looking for sunbeams in cucumbers, and that the present age is mightily given to abstract notions, and a good deal of ophthalmic, histiologic, and bamboozologic nonsense, at both sides of the channel, we will say at once that this paper of the obstetric attendant at St. Mary's Hospital is one of no little value, and opens up some new notions of practice of very great value. Need we say in practice what a large amount of patients come to us with uterine diseases; how very marvellously in the dark in hysterical, epileptical, and all diseases of the lumbago tribe in females, we too often find ourselves? Any key, then, to uterine diseases must be of value—any generalisation of a heap of crudities left us by

the last generation of old women, or, shall we say it under favour, what is worse than old women, according to Lord Palmerston, old men. Even our recondite College of Surgeons has at length recognized the existence of such a thing in the world as obstetrics, though long since it looked with favour on—what shall I say—homœopathy. Midwifery, of course, is not the most scientific department of the profession, but it is a grave question whether it may not be made so. Tyler Smith is known here favourably, as having first suggested the connexion of labour itself, and the various phenomena of labour, with Marshall Hall's doctrine of the reflex and excito-motor system of nervous action. In the paper under notice, he seems to have planted his scalpel somewhat farther into chaos, and tells us how the os uteri itself is a *large open gland*, the chief seat of leucorrhœa and of the many ills to which feminine flesh is heir, existing at this point of the utero-vaginal tract. An exaggerated idea which will correct itself, is perhaps sometimes better than no idea at all; so that Hassall's beautiful plates exhibited at the society, which makes it plain to the "meanest capacity," will ultimately settle down into new and valuable notions of this part of the economy. Arthur Hassall, perhaps we may say, is, body and bones, the "Analytical (or what's this is it is?), Sanitary, and Microscopic Commission" of the *Lancet* on nutmegs and infusoria; and a man well qualified for microscopic inquiries on "Ovula Nabothi," and the ten thousand follicles of which the healthy virgin cervix uteri is made up—according to these researches.

In the "Marble Halls" of Sir Patrick Dun's it will be something new for Dr. Montgomery to learn that "Ovula Nabothi," which, in his very valuable lectures, he treated as obstructed follicles, our clearer lights in London put down as an "eruptive disease" analogous to a cutaneous disorder; that in practice this explains why they are more frequently found in women of strumous habits and leuco-phlegmatic temperament; why many similar affections of the vagina and uterus are best treated constitutionally; not forgetting, in all proper cases of ulceration, nitrate of silver to the os uteri topically, about which in London we have had an "ullabolloo" on the part of men who knew not one single thing about the matter. The glandular character of the cervix will, in fact, suggest to practical men many matters of the very first importance. It would be curious, did time permit, to go back into the dusty graves of some of our old authors and see did they not think the "os tincæ" a gland, or highly glandular. We witnessed a large piece of the tongue not long since removed at the London Hospital by a wire made red hot by the electric battery, and thought curiously how this very manifest improvement bears a likeness to amputations as practised scarcely a hundred years ago with red hot knives. Could we stop reciting always old authorities, and kick manfully out into deep water, we might do something new, or re-discover the wonderful truths of our forefathers. Compression in aneurism, chloroform, Marshall Hall's excito-motor system, the stethoscope, the many facts revealed by the microscope, our perfect knowledge now at length of the anatomy of the brain and spinal axis, the value of tartar emetic in febrile diseases, and many other points familiar to the practical man, sufficiently show what a harvest, in spite of jealousies of journals, has been gathered into the garner.

On some points, of course, we are still quite at sea. The distinction of malignant and non-malignant tumours, phthisis, and equitable insurance offices. On these, it is expected, in official quarters, we are to go on till the day preceding the day of judgment. In Edinburgh a crusade has been commenced against humbug and dishonesty, and in their "colloquial" moods, it is hoped, much good will be effected: if shams are to be put down, it is perhaps by the light feathery artillery of the press. Matters of serious grave importance come every day under consideration; only at the Medico-Chirurgical and

other societies, however, can any approximation to the truth be obtained. The unhealthy scrofulous flush on the cheek of our hebdomadries, is as much like the flush of wholesome science as opera goblets and painted claret are to the veritable wine, so to speak, of our tables.

Mr. Luke not long since stated he only lost two out of forty patients at the London Hospital on whom he had operated for hernia without opening the sac, though previously one in three was a fair average. Mr. Fergusson has given us his experience on the point; Mr. Bransby Cooper also. Some of our young men could settle the thing in ten sentences, from an analysis of all the cases published, like Marshall Hall, or Hassall, or Bennet, or Tyler Smith; however, he would be blown to small bits if he did. The quack gentlemen with their stages and medicines, the pharmaceutical chemists like the plague of frogs spoken of by Moses, the homœopaths, may all settle down on the land, and bask in the sunshine of a half year's subscription; but in London any man that attempts anything new or useful is a doomed man.

Some cases of "morbus coxæ" at St. Thomas's, have given Mr. Solly occasion lately to make some clinical remarks in addition to the facts already established by the Dublin School, where the disease is so thoroughly understood. The remarks of Mr. Solly are excellent. He thinks, however, caries of the head of the bone may occur without symptoms: he thinks it essentially scrofula. He is, of course, for sea air, cod-liver oil, issues, &c. We have met pharmaceutical chemists and general practitioners treating the disease, who knew as much about it as of the inscriptions on the five legged bull of Mr. Lazard in the British Museum: ankylosis, atrophy, death, and a long bill, the normal law of things in their minds. In eye diseases, what sad havoc have we not witnessed, where one-third the money given to poor Dalrymple, Alexander, or Wharton Jones would have set the patient all right. The pharmaceutical chemist, however, if he has very large pharmaceutical bottles in his window, and subscribes to the *Lancet*, will do every thing, except snuff the moon.

Of 4091 persons admitted into the Small-pox Hospital with small-pox, considerably more than one-half had been so-called vaccinated; and any one who has ever witnessed this operation among the pauper classes of the population in London by the chemists' assistants, must mourn for Jenner and vaccination and the shifting sands on which our statistics of this disease are built up. Any kind of milky pustule is got hold of, and any kind of children with scrofula or cutaneous diseases are haply induced to undergo an additional dose of some horrid infection, placed in the current of their absorbents. Gregory is for restricting inoculation, and wishes very properly for some change in the law of 1840; but forthwith it becomes a party question, only equal in virulence to whether bitter ale has got strychnine in it or Mr. D'Israeli is to jump into a quart bottle. Many matters of this sort the good common sense of the profession will always be proof against in the higher walks of practice, but among the middle and lower classes in all our large towns, medicine is a solemn mockery; and the deterioration of the health of the present generation from scrofulous and malignant diseases, is one of the most painful facts in London hospital practice. In all towns, of course, there are various shades of practice, and various shaped diplomas; but, somehow, in London the men without any conceivable diploma at all, are those who derive the largest practice. Mr. South complacently tells parliament the diploma of the college is merely permissory or honorary; giving the luckless M.R.C.S. no right at all to practise. If a barber, no doubt the learned ex-president would find some archæological statute still in full force.

I am quite aware it would be more amiable and more valuable, individually, to cease complaining, and get up into that heaven of invention spoken by Shakespeare, and practised by many of our flash writers here. But there is little of real value after all in medicine or morals but the diamond grain

of truth at the bottom of the rubbish one sees around him. Medicine as a noble art here is unknown. The good men live in bodily terror of rival reviewers. From France, and Germany, and New York, and even old Edinburgh, new ideas and researches pour in upon us; in Dublin, too, one watches with no little interest the valuable and most useful facts of your pathological school, and the sterling good sense indicated in your journal; but with Hassall, Tyler Smith, Marshall Hall, Gregory, and scores of such men, it is a perpetual warfare, and medicine itself is like nothing I remember but the sad daughter of Hippocrates in poor old Sir John Mandeville, occupying her island territory in the shape of a dragon a hundred fathoms long, and waiting in weariness of soul for the day some adventurous knight shall restore her to her once comely shape.

### ARTIFICIAL EYES.

We do not think that Surgeons are fully aware of the value of this resource as a means of relief from a most distressing deformity; and we know that the public at large are altogether unacquainted with its merits, and incredulous as to the possibility of its application. Our object in alluding to the subject is to dispel all doubts respecting the matter, by assuring persons interested in it that there is no question whatever as to the success of the contrivance; in fact, artificial eyes are as easily adapted as artificial teeth, and are as easily worn; nay, perhaps they have been used before substitutes for lost teeth were generally employed. To those unacquainted with the thing, it is necessary to say that it is a shell of vitreous material formed and painted to match the sound eye, and that it is slipped in between the lids and the remaining portion of the injured one. Here, if properly formed and fitted, it remains, causing no more inconvenience than the gold plate of artificial teeth does to the gum, and affording a relief from deformity much more conspicuous than that generally derived from the dentist's skill. We are induced to call attention to the subject at the present moment in consequence of a communication from M. BOISSONNEAU, late of Paris, but now of London, stating that he proposes to visit Dublin at the latter end of this month to offer his services in this department of mechanical surgery, which he has much improved. Great difficulty having been hitherto experienced by Surgeons desirous of obtaining artificial eyes for patients in this country, in consequence of the want of a means of obtaining suitable ones from the makers in Paris and London, we announce this for their information, without entering into details or expressing any opinion as to the comparative merits of contrivances upon which M. BOISSONNEAU will doubtless in process of time offer every information. As to his method of doing business, or the arrangements he proposes to make with Surgeons in attendance on the cases requiring his aid, we know nothing, and have therefore only to say respecting this point that people with money in their pockets are not to expect gratuitous services in this more than any other department; in other words, people requiring artificial eyes must pay not only for the article itself but for the safe and perfect fitting of it.

### MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

DR. J. F. DUNCAN, Treasurer, thankfully acknowledges the receipt of the following sums since last report:—

Dr. Geary, Limerick	...	...	£1 0 0
Dr. Clayton, Athy	...	...	1 1 0
Dr. Nalty, Clare-street	...	...	2 2 0

From Executors of the late James Parker, Esq., of Limerick, first instalment of his bequest of £100, 71 8 7

19, Gardiner's-place, Aug. 16, 1852.

A REVIEW OF RECENT RESEARCHES IN  
PATHOLOGICAL HISTOLOGY:Including the Diagnosis of CANCEROUS and CANCROID  
Diseases.

By ROBERT D. LYONS, M.B., L.R.C.S.I., M.R.I.A., &amp;c.

Dublin: Hodges and Smith; also to be had of Fannin and  
Co., Grafton-street.

G. OLDHAM and Co., Pharmaceutical Chemists and  
Apothecaries, 107, Grafton-street, Dublin, corner of Suf-  
folk-street (Agents for the sale of Mr. Coxeter's Surgical  
Instruments), invite the attention of the Medical Profession  
to their present Stock of Instruments, all of which are manu-  
factured on the most approved principles.

Superior Dissecting Instruments well worth the inspection  
of the Student.

## THE COMPOUNDING DEPARTMENT AT

## G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregu-  
larity, and obtains the especial care of the Proprietors. Anxious  
to give satisfaction to the Medical Profession, G. O. and Co.  
commenced dispensing medicine with the resolution to devote  
to it their unremitting personal attention; to employ none but  
experienced Assistants; to render prices moderate as it is  
possible for any house that confines itself to the best articles;  
and to supply, either in the simple state or in combination,  
the most effective medicines that can be procured or prepared,  
and on which the Practitioner may rely.

## BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &amp;c.

G. O. and Co. continue to be supplied with the FOREIGN  
MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city  
and suburbs, and along the line of the Kingstown Railway,  
at any hour, free of charge.

Just published, 8vo, pp. 96, price 2s. 6d.,

## A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature  
of its Opacities, and the Operation for its Removal by Ab-  
sorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College  
of Surgeons, and one of the Surgeons of the  
City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

## THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office  
of the MEDICAL PRESS, 15, Molesworth-street. London:  
John Churchill, Princes-street, Soho.

## TO PHYSICIANS, SURGEONS, AND DRUGGISTS

## BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than  
the Emp. Lyttæ. P.L., easily applied and removed, and will  
not produce stranguy or troublesome after-sores. It has  
received the sanction and commendation of many of the most  
eminent Practitioners in the kingdom.—In Tin Cases, con-  
taining twelve feet, 6s. 6d.; and small Cases of six square feet,  
3s. 6d. each.

## BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all oint-  
ments as a dressing for Blisters, and may be called a compa-  
nion to the above.—In Tin Cases, containing twelve square  
feet, 1s. 6d. each.

Extracts and Editorial Note from the New York Journal of  
Medicine.

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar  
claims to our notice in the inflammatory diseases of females  
and children, in whom the unpleasant consequences which so  
often follow the application of the Emp. Cantharides are most  
apt to occur. We have found it a reliable and peculiarly  
safe vesicant, and from the many trials we have given it, we  
are satisfied that it deserves the attention of the Medical  
Profession.

"Accompanying this article is a very simple and neat  
dressing."

From the Medical Examiner and Record of Medical Science  
for May, 1850, published in Philadelphia.

"We have received from Mr. George D. Phelps of New  
York specimens of Brown's Cantharidine Blistering Plaster  
and Dressing, with which our readers are doubtless familiar  
as a new and exceedingly neat preparation, easy of applica-  
tion and certain in their effects. We have given them a fair  
trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital,  
Fort Pitt, Chatham, reports that Mr. Brown's Blistering  
Tissue has been used extensively in the Military Hospital,  
has been found effective as a vesicatory, when carefully ap-  
plied, and has not been productive of any degree of stranguy.

"ANDREW SMITH, M.D.,

"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,

"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley  
Fields Chemical Works, Wolverhampton; and all wholesale  
and retail Druggists and Medicine Agents throughout the  
British Empire.

## SUCCESSFUL REMOVAL OF A PAROTID TUMOUR.

By ROBERT L. MACDONNELL, M.D.,  
Surgeon to St. Patrick's Hospital, Lecturer on Surgery,  
St. Lawrence School of Medicine, &c., Montreal.

ABOUT the middle of June, 1851, my friend, Dr. Mount, requested me to examine a young man from the country. The patient's face and head were concealed from view by a large piece of linen, which, on being removed, disclosed a frightful phagedenic-looking ulcer, which had almost completely removed the left cheek, exposing the teeth of the upper and lower jaws, the side of the tongue, &c. From this ulcer exuded a foul fetid discharge, mixed with saliva and particles of half-masticated food.

The edges of the ulcer were irregular and sloughy, but not indurated, and the parotid gland appeared to be implicated in the disease, for it was enlarged and prominent, and advanced down for nearly an inch below the level of the angle of the lower jaw. At this examination, the patient being in the street near my own house, I concluded that the ulceration had been caused by malignant disease, and advised that palliatives should be employed, and no attempt at eradication should be resorted to. Being at the time on my way to an urgent case, I paid no further attention to that now under consideration. Some time after, Dr. Mount mentioned to me as a very curious fact, that he had learned from a friend of the patient's, that the ulcerated aperture had become closed, and that the disease had been arrested without any application whatever being employed. The patient entered St. Patrick's Hospital under my care in the month of February, 1852, when the following particulars were ascertained, of which we had hitherto been ignorant:—The disease commenced about two years previous to our first examination, in the form of a small, hard tumour, situated in the region of the *socia parotidis* gland. This tumour gradually increased, and soon attained the size of an egg, the parotid itself undergoing increased size, and becoming hard and painful subsequently. During the progress of this tumour, much

pain was experienced in all the movements of the jaw, in the act of mastication and speaking, and laughing and yawning were excessively distressing. He also observed that symptoms indicating paralysis of the portio dura manifested themselves—the mouth was drawn to the opposite side, and in eating, portions of food used to lodge between the cheek and gums, &c. Not obtaining any relief from regular practitioners, he sought advice from an itinerant "cancer doctor," who applied a plaster, which was allowed to remain on the tumour for forty days, and at the expiration of this period, the original tumour and the greater portion of the cheek sloughed away. It was soon after this event that he presented himself to Dr. M., who then brought him to my residence, but being at the time much hurried, the cursory examination already described was all that was made, and the patient returned home immediately. According to his statement the ulcerated surface quickly granulated, the chasm in the cheek was rapidly filled up, and the parotid tumour remained stationary at first, but recently had commenced growing, and was extending downwards below the posterior digastric space, and backwards under the insertion of the sterno-mastoid muscle, and this extension of the disease was accompanied by severe neuralgic pains along the superior branches of the portio dura, and also along the course of the occipital and spinal accessory nerves; he had also severe constant pain in the ear, and deep seated pain in the locality of the glenoid fissure, and adjacent parts. The tumour was hard, regular on its surface, not painful to the touch, moveable to a certain extent, particularly above, the integument covering it was healthy, not presenting anywhere a malignant aspect, and apparently the communication between this tumour and the region around the former one, was quite cut off; in other words, it appeared as if it had been, from the commencement, a separate and distinct growth. The superficial portion of the tumour gave one the idea of the whole mass being about the size of a turkey's egg, but its exact dimensions could not be determined accurately. The patient's appearance was remarkably healthy, and all who saw him were surprised to see one who was to all appear-

ance in rude health, the probable subject of malignant disease. As both the patient and his friends were extremely anxious to have the tumour removed, I acceded to their request, the more willingly as the result of the cancer plaster proved a strong disposition in the system for repair, and the duration of the disease, as well as its being so little influenced by the irritation immediately around it, seemed to justify me in expecting a successful issue from the operation, provided the tumour *could be removed*. Moreover, the cicatrix which followed the sloughing was firm and good, and exhibited no trace of degeneration, and there was no enlargement of any of the lymphatic glands in the neighbourhood. Accordingly, on the 13th of March, I operated in the following manner:—The tumour was exposed by dissecting off the integument in three flaps, converging at a centre which corresponded to the most prominent part of the tumour. This being done, the difficulty of the operation commenced, and that consisted in detaching the superficial cervical fascia from the growth, for it had become condensed, hard, and gristly, and bound down the growth so firmly, that at one time it appeared almost impossible to detach it from the mass, so as to enucleate or dissect it out. Some idea may be formed of the resistance this apparently insignificant structure presented, when I state, that I was obliged to have recourse to a second scalpel, the first (a new one by Weiss) having been soon blunted. The more I cut, the deeper I got, but no nearer, as it seemed, to the isolation of the disease, when it occurred to me to use a director, and having shoved it under layer after layer of the fascia, they were in succession divided. As soon as I had succeeded in isolating the circumference of the tumour, its extraction from its deep-seated relations next occupied attention, and in this stage the edge of the knife was kept close upon the tumour, and all suspicious structures carefully examined before being divided, and the handle of the scalpel was freely used. It was now found that the disease went down farther on the neck than was supposed, and that it also sent a process dipping into the substance of the sternomastoid muscles, where the spinal accessory nerve passes through that muscle (which it did in this instance much higher than usual), and proceeded in a posterior direction until it impinged upon the cervical plexus, which nerves, together with the spinal accessory, were fully exposed in the progress of the dissection, and seen by all present when the tumour was removed. Some parts of the disease which dipped into the net-work of the plexus were carefully dissected out, and a portion of the sterno-mastoid was removed along with them. The mass being removed, the finger passed freely upwards under the zygoma, under the angle of the jaw, between the pterygoids and inferiorly to the cervical plexus; it could also be passed into the fossa corresponding to the glenoid cavity, at the bottom of which the strong pulsation of the external carotid was very perceptible, and the styloid process and the muscles attached to it were likewise observed. No other structure was perceptible. A small degree of hæmorrhage from the surface took place at the beginning of the operation, and only two small vessels, branches of the anterior auricular and occipital (?) required ligatures.\*

On examination, the diseased mass presented the character of a fibrous tumour, in some points degenerating into scirrhus; this latter feature was not, however, strongly marked. It was much smaller than was supposed before the operation, for a great part of the size of the tumour was formed by the sterno-mastoid which overlapped one portion of it, and was intimately connected with another part.

The wound was filled with a pledget of wet lint, and the

flaps brought loosely together. Five hours after the wound was dressed, some oozing had taken place, and one more small twig required a ligature. The edges of the wound were now brought into contact by means of sutures, a space in the centre being but loosely united, that the discharge might freely escape. A compress and bandage served to obliterate the cavity, and were retained for three days, when the sutures were withdrawn, and union by the first intention was found to have taken place to a great extent. It would be useless to detail the changes of treatment which the varying condition of the wound suggested, suffice it to say, that at the end of sixteen days he was discharged at his own request, the wound being then perfectly healed, and he himself free from all his sufferings.

There are some points connected with this case not devoid of interest to the practical surgeon, to which allusion will now be made; and first I shall speak of the opinion so generally advanced by anatomists, that the parotid gland cannot be extirpated, and which is as strenuously denied by surgeons. Not only in this, but in many other particulars do we find that the skilful anatomist is not always the best guide to the operating surgeon; and that diseased anatomy frequently runs counter to normal anatomy, and the facility or difficulty with which an operation may be performed, cannot always be determined with exactness by our knowledge of the normal structure in which the disease has originated. Can a stronger proof of the truth of what I now advance be adduced than the fact, that it was necessary to tie but three small vessels in the operation under consideration, when we reflect upon the numerous arteries that supply, and pass through the region, in which the mass lay.\* It is needless, then, to advance the certainty of alarming hæmorrhage as an argument against such operations. But it has been said that in the instances of supposed removal of the parotid, it was only the socia parotidis that was extirpated. This may be so in some cases, but in the example now before us, the mass extended into most of the recesses usually occupied by the parotid, and advanced into regions in which that gland is never found in its healthy condition, and as neither the parotid itself, nor any part of it, was noticed during or after the operations we must infer either that it had degenerated into a morbid mass, although a change to which the salivary glands are by no means prone, or that it had been partly absorbed by pressure, some parts of it, in the deeper regions between the external and internal carotid, around the masseter, and deep at the glenoid fissure, still remaining. Such may have been the case, but I cannot consider it as similar to those in which a tumour has been peeled off the parotid; one of which has recently been published by an eminent surgeon, as a type of parotid tumours, but of which variety most surgeons have seen examples.

This case also exemplifies the difficulty occasionally experienced in determining the size of cervical tumours, and the direction they take; for I need not say, that I did not suppose the disease took so irregular a course, or was connected with so many and such important parts, though I was prepared to abandon the operation at any stage of the proceeding, if impossible to complete it without subjecting the patient to too great a risk. In illustration of this difficulty I may mention that my friend and former clinical clerk, Dr. McCallum, informs me that he recently saw Mr. Lawrence at St. Bartholomew's obliged to abandon an operation, in a case of cervical tumour, after he had proceeded to a considerable extent, in consequence of the great and unsuspected attachments of the tumour.

On the other hand, the surgeon not unfrequently meets with tumours which appear to be deeply attached, and which, on the integuments being removed, admit of easy extirpation. On this subject, more extensive clinical observation is much needed.—*Canada Med. Jour.*

\* Had the carotid been tied previous to the operation, as recommended by Mott and others, this immunity from hæmorrhage would, no doubt, have been attributed to this precautionary measure.

\* The arteries that may be wounded are, in addition to the carotids, the transverse facial, the temporal, the auricular, the mastoid, the stylo-mastoid, the occipital, the internal maxillary, the inferior pharyngeal, the lingual, and the facial.—*Malgaigne's Operative Surgery*, page 368, *Am. Ed.*

## ON THE USE OF MANGANESE AS AN ADJUVANT TO IRON.

M. PETREQUIN quotes various authors to prove that manganese is a normal constituent of animal and vegetable tissues; and believes that wherever iron is present in appreciable quantity, manganese coexists with it. Hence iron alone will not always succeed in blood-diseases. M. Pétrequin has observed many cases of chlorosis, which have resisted iron as obstinately as anæmia connected with cancer or organic degeneration. Other cases again, after deriving a certain amount of benefit from iron, remain stationary. Others again appear cured by iron, but the cure is not permanent. The remedy required in these cases, M. Pétrequin finds to be manganese. He does not give it or iron alone; but combines them.

It is especially in *diseases of the blood* that ferro-manganic medicines are useful. They have a special action on the vascular apparatus, on the formation of the blood, and on the circulating fluid itself. They do not act merely as tonics or astringents; but are regenerators of the blood. They have succeeded admirably in anæmia following hæmorrhage, operations, polypi, metrorrhagia, &c., also in the chlorosis attending puberty, which is a more common disease than is generally supposed, and occurs even in males. M. Pétrequin has also frequently found the combinations of iron with manganese of benefit in the diseases of women at the critical period. He has often seen, in these subjects, *metrorrhagia*, accompanied with an aspect of the surface which would lead to the suspicion of organic uterine disease: the hæmorrhage, however, was but a complication, and the patients, apparently in a hopeless state, have recovered under the use of ferro-manganic preparations, conjoined with tonics and ergotine.

In *amenorrhœa* and *dysmenorrhœa*, the patients often imagine that they require to be bled; but care must generally be taken not to comply with this request. M. Pétrequin has more than once seen cases of amenorrhœa with severe chlorosis, in which it has not been desirable to hasten the appearance of the catamenia—the consequent loss of blood aggravating the disease. The general state of health must here be carefully attended to. Œdema of the lower limbs sometimes occurs in these cases; but it is a less severe complication than when it attends metrorrhagia. It often disappears, as the patient recovers, under the use of iron and manganese.

These medicines are no less efficacious in the treatment of *anæmia* resulting from prolonged intermittent fevers, prolonged suppuration, strumous, syphilitic, or cancerous affections, phthisis, &c. Pills and the syrup of the iodide of manganese and iron are preferable in these cases.

In all these cases, the ferro-manganic preparations do not merely act on the stomach and nervous system, but they are absorbed and assist in the formation of hæmatosine and new blood-globules, so as to restore the blood to its normal condition. Their effect in this way is greater than that of iron alone.

In the *functional affections of the heart* connected with chlorosis and anæmia, and which must not be mistaken for organic disease, a combination of iron and manganese with digitalis and other moderators of the heart's action is advantageous. The same remark applies to the *functional disorders of the lungs*, attending the same constitutional states. *Disordered states of the nervous system* are intimately connected with those of the blood. M. Pétrequin has found that the ferro-manganic preparations succeed well in these, even though uncomplicated with chlorosis. He, as well as M. Gubian, has observed that iron is here better tolerated when combined with manganese. He has also seen benefit from the use of iron with manganese in many cases of *dyspepsia*, *gastralgia*, and *gastro-enteralgia*. Nervous affections of the digestive organs are often the result of chlorosis; and, where stomachics and cinchona have failed, iron has often been found (especially the carbonate, by some English physicians) to be of service. *Gastrodynia* complicating chlorosis has often yielded to the use

of ferro-manganiferous water, and to pills of carbonate of iron and manganese.

In *nervous affections connected with exhaustion* from venereal excesses, onanism, rapid growth, &c., as well as in leucorrhœa, diabetes, &c., M. Pétrequin has a high opinion of these medicines. He is continuing his researches on their action in certain cases of sterility from asthenia, and in some hyposthenic affections of the scalp, such as early baldness, alopecia, &c.

M. Pétrequin has confined his observations to a limited number of the ferro-manganic preparations; and has made many observations before publishing the formulæ which he finds most useful. Having found, even at an early period, that the medicines were liable to adulteration, he has availed himself of the assistance of competent pharmacists. Since the publication of his first memoir, in 1849, these medicines have been extensively used in the south of France and in foreign countries.

The formulæ are few and correspond to the preparations of iron generally used in France. They are: 1. *Pills* of carbonate of iron and manganese, or of iodide; 2. *Lozenges* of lactate of iron and manganese; 3. *Syrups* of lactate or of iodide of iron and manganese; 4. *Ferro-manganic chocolate*; 5. *Effervescing solution* of iron and manganese.

It has been observed that manganese not only preserves water, but purifies that which has undergone change—(Martin-Lauzer). Ferro-manganic waters (of which there are many in France and other parts of the continent) can be preserved and carried to a distance;—which cannot generally be done with simple ferruginous waters.

M. Pétrequin commences by giving a powder of iron and manganese, with some vinous drink; he then administers two pills daily, one before breakfast and one before dinner, replacing them soon by the lozenges. The syrups and chocolate complete the treatment. He gives the medicines at meal time. The syrup he gives before breakfast, in doses of a teaspoonful; and he finds it useful to administer directly after it some infusion of centaury, or of chamomile flowers and orange.

Large doses are unnecessary and useless; for they are liable to produce irritation of the stomach and exhaustion of the nervous system; and the reparation of the blood is slow and progressive, and cannot, even were it desirable, be effected rapidly. Besides the iron and manganese are not absorbed in any greater quantity, if large doses are given.

## PREPARATIONS OF MANGANESE AND IRON.

M. BURIN-DUBUISSON of Lyons, who prepared most of the ferro-manganic combinations used by M. Pétrequin, has published an interesting *brochure*, in which he gives the necessary details relating to the subject. The following formulæ are extracted from it:—

*Powder for Effervescing Solution of Manganese and Iron.* Take of coarsely powdered bicarbonate of soda, 20 parts; tartaric acid, 25 parts; powdered sugar, 53 parts; finely powdered sulphate of iron,  $1\frac{1}{2}$  part; finely powdered sulphate of manganese,  $\frac{3}{4}$  parts: mix carefully, and keep in well stopped bottles. A teaspoonful is mixed with each glass of wine and water drunk during meal time.

*Pills of Carbonate of Iron and Manganese.* Take of pure crystallised sulphate of iron, 75 parts; pure crystallised sulphate of manganese, 25 parts; crystallised carbonate of soda, 120 parts; honey, 60 parts; water, a sufficient quantity. Pills of 20 centigrammes (3 grains) are made; they keep easily, without becoming oxidised, in well-closed vessels. From two to four are given daily.

*Ferro-manganic Chocolate.* One part of carbonate of iron and manganese is first mixed with four of sugar, and divided into large lozenges; of these, 100 parts (grammes) are mixed with 500 of chocolate paste, in the preparation of which 100 parts of sugar have been left out. This will make 800 lozenges, each of which contains about 3 centigrammes (nearly half a grain) of carbonate of iron and manganese. The chocolate decomposes the hydrated carbonate of manganese and iron of the saccharate into hydrated sesquioxide of iron and manganese; there is no metallic taste.

**Syrup of Lactate of Iron and Manganese.** Take of lactate of iron and manganese, 4 parts; powdered sugar, 16 parts; rub together, and add of distilled water, 200 parts; dissolve rapidly, and pour into a mattress over a water-bath, containing 384 parts of broken sugar; filter the solution. This syrup contains about 15 parts of lactate of iron and 5 of lactate of manganese in 3000 parts. One or two spoonfuls are taken daily.

**Lozenges of Lactate of Iron and Manganese** are made by adding 20 parts of the lactate to 400 of fine sugar, with a sufficient quantity of water. The mass will make 840 lozenges; of which six or eight are taken daily.

**Syrup of Iodide of Iron and Manganese.** M. Burin-Dubuisson forms a solution of iodide of iron and manganese, in the proportion of one part by weight to two of water; the proportion of the salts is about three of iodide of iron to one of iodide of manganese. Six parts of this are mixed with 294 of simple syrup; of this, M. Pétrequin gives one or two spoonfuls daily.

**Pills of Iodide of Iron and Manganese.** Take of the official solution prepared by M. Burin-Dubuisson, 16 parts (grammes); honey, 5 parts; some absorbent powder, 9½ parts. Divide into 100 pills. The honey and the solution are first mixed, and evaporated at first rapidly, then more slowly, to ten parts. Then add the powder, and divide the mass into four parts, which must be rolled in powder of iron reduced by hydrogen; each of these must then be divided on an iron plate into 25 pills, and again rolled in the iron powder. Finally, they are covered with a layer of tolu, according to M. Blancard's process.

All these preparations must be made very carefully. M. Burin-Dubuisson has ascertained that the commercial salts of manganese frequently contain copper, and even arsenic; he hence insists on the necessity of calcining the sulphate of manganese, twice, or more frequently, at a dark red heat, and of carefully testing the solution.—*Lond. Jour. of Med.*

## NEW FORM OF VARICOSE ANEURISM.

By M. BERARD.

Two different lesions may follow as a consequence of the simultaneous wound of a contiguous artery and vein. In certain cases the blood passes directly from the artery into the vein; the latter becomes dilated either in the exact locality of the wound, or at some distance between it and the nearest branch. This is *aneurismal varix*. In other cases a tumour is formed, the size of which is limited by the surrounding cellular tissue, and into which the arterial blood penetrates. The communication of the tumour with the vein gives it some other peculiarities, and it is called *varicose aneurism*.

Writers have generally mentioned the following as the characters of varicose aneurism:—A canal, of greater or less length, runs between the artery and the vein, establishing a communication between the two vessels; at some point there is a sac, bounded by cellular tissue. This lesion, which is more rare than the other, has only been submitted to dissection three or four times, and therefore M. Berard reports the following example:—

A man, aged 40, who was in the habit of being bled for some cerebral affection, had the artery opened by mistake in 1840; a bandage was placed on the puncture. In the morning after, the man complained of a pain in the arm, with the sensation of burning along the course of the vessels. Attributing this to the bandage, he loosened it, when the limb began to swell; the tumefaction reached the shoulder and wrist, the skin becoming at length quite black; soon after pulsation became perceptible in the fold of the elbow and lower part of the arm.

After the tumefaction had subsided, a soft fluctuating tumour was found on the inner side of the tendon of the biceps; its pulsations were distinct and isochronous with those of the arteries. The entry of blood into the tumour was accompanied with a distinct bruit. In addition to this a bruit was propagated along the veins, but of a distinctly different character from that which was heard in the tumour. From these signs the author at once per-

ceived that he had a combined case of varicose aneurism and aneurismal varix. After a variety of treatment he found it necessary to tie the brachial artery.

Compression being made accordingly in the superior two thirds of the track of the vessel, an incision was made in the bend of the elbow, exposing the anterior portion of the sac; this was likewise opened, giving issue to dark fluid blood, mixed with clots. The upper portion of artery when it entered the sac was then ligatured. It was now found that, although the vessel was tied, blood continued to pour into the sac from below, and the author with great difficulty found the lower opening of the vessel, which was hidden from view by the interposition of the vein; in fact the exact condition of the parts was this:—The artery presented a large transverse wound on its anterior surface; in front of the artery lay the vein, glued to it, and itself pierced beneath by a wound corresponding to that of the artery, and above by another of the same dimensions. Above this was the aneurismal pouch, so that the blood from the artery traversed the vein in reaching it.

The explanation of these lesions given by the author is, that during the venesection the vein was pierced through, and the artery opened; the lower puncture in the vein remained open, while the upper cicatrized, and an aneurismal varix ensued. After a time the impulse of the blood upon the upper surface of the vein caused the puncture to reopen, and an aneurismal pouch then formed in the external coat of the vein and cellular tissue.—*Memoirs de la Société de Chirurgie.*

## ON THE TREATMENT OF HIP-JOINT DISEASE BY THE STRAIGHT SPLINT.

By S. COOPER FORSTER, F.R.C.S.,  
Surgeon to the Surrey Dispensary, &c.

THE author advocates a measure of great importance, first, as he informs us, introduced by Mr. Key, and in his own practice found eminently successful. The plan is not unattended with some little trouble to the surgeon, and requires constant attendance and watching, and therefore perhaps a numerous class of patients will be frequently neglected, and a class indeed to whom it is of the greatest importance that a very serviceable leg should be obtained. From the author's experience amongst the poor, what with previous neglect and misapplication of remedial measures, or the total indifference of parents, many children and young lads are doomed to drag on either a miserable existence, a burden to themselves or families, or terminate their lives at a premature age: many cases of disease of the hip-joint in all its stages, are often neglected by the surgeon, from a belief that little can be done except place the patient in a recumbent posture, with perhaps a pillow or so beneath his knee. Now besides the simple horizontal posture, the author believes the greatest amount of good may be accomplished by also applying such local measures as will ensure the patient a useful member, after the subsidence of the inflammatory symptoms, and not supposing that Nature dictates the proper position in which the limb should be placed for future use, though she undoubtedly fixes it in the most comfortable posture for the present. For example, he remarks, no one can believe that the bent position is the most useful one for an ankylosed knee-joint, nor indeed is it, as far as his experience goes, the most useful for the hip-joint, whether perfectly fixed or not; and yet it is the position which all the cases of disease of the hip-joint would acquire if left to Nature; and, indeed, two joints become contracted, inasmuch as the knee always is flexed likewise; and no one can doubt that the straight would be most useful. The treatment the author advocates is not by any means easily applied in what is called the third stage of the disease, where suppuration is established, and an opening or openings formed; but as it is more common to see this complaint in the first two stages, and in either of them the straight position is with very little trouble obtained, the treatment is of course most applicable at those times.

The object the author has especially in view, by the plan of treatment with the straight splint, are as follows: 1st, to relieve pain by obtaining the most perfect rest; 2nd, to prevent abscess forming, or if matter has formed, to determine the point at which it shall come to the surface; 3rd, the greatest advantage, and the one to which he more particularly wishes to draw the attention of the profession, is the future usefulness of the member.

Rest, he observes, is of course the first thing to be sought for in an inflamed joint, and the patient will take care to obtain it by some means or other, and in no way is it more effectually obtained than by fixing the body and leg as one piece, and thereby most entirely preventing motion in the great seat of it between the body and extremities—viz., the hip-joint. Now the straight splint, fixing as it does around the hip, thigh, and leg, is the only means whereby that advantage is thoroughly obtained; the usual practice of placing a pillow beneath the knee, or a large piece of millboard or gutta percha around the joint only, or other contrivances according to the ingenuity of the surgeon, fails to do so in an effectual manner, and never can give that perfect rest which the splint affords.

The second object to be attained by the use of the straight splint is the prevention of suppuration, or if pus is formed, by the perfect rest which is obtained, to induce absorption, or at all events to determine the point at which the matter shall come to the surface. The author informs us that during the time he was dressing for Mr. Key, and when he first proposed this plan of treatment, two cases came under his care at Guy's Hospital, in both of which matter had formed previous to admission, the straight splint was applied, and in each case the abscess burst on the fore part of the tensor vaginæ femoris. These cases were alluded to in Mr. Key's remarks, in the *Medical Gazette*, concerning this mode of treatment. As regards this question, the author admits that there is some difficulty in deciding, and it is one which must always be open to doubt, as we so frequently see matter point at all parts around a diseased hip-joint, apparently without any reason; at all events he thinks the fact of three cases, two of which matter came to the surface, and one in which it nearly did so, no tendency to pointing taking place at any other place, is a remarkable coincidence, and one well deserving of notice.

3rdly, and this is the greatest advantage which the application of the straight splint holds out—viz., the future position of the limb. When the surgeon is called to a patient with hip-joint disease in either of the first two stages, we almost invariably find them lying on the opposite side to that which is affected, with the diseased thigh bent upon the pelvis, and the leg on the thigh, a position anything but the most likely to be of permanent usefulness should ankylosis occur, or such an imperfect amount of motion as usually follows acute mischief in any joint; the author, therefore, whenever called to see a patient labouring under this disease, after copious bleeding by leeches over the joint, places them on their back, and cautiously and carefully brings down the thigh to the level of the bed, and thereby straightens the knee. But one caution, he remarks, is necessary to be given in so doing; so tenacious is the hip-joint, when in this state, of any even the slightest motion, so firmly have the muscles round about fixed the head of the bone in the acetabulum, that in doing so the spine frequently becomes arched about the lumbar vertebræ, and in reality, the thigh is at the same angle with the pelvis as it was before the leg was touched; this, however, he has generally found relieve itself very shortly. The splint, when placed on for the first time, soon requires readjusting, and upon the second application, should the bandage be starched, the whole pelvis and thigh becomes one solid mass, and preserves the most perfect rest. When the patients have the splint removed, and first get up, the author enjoins caution that they do not use the unsound leg until they have cautiously and carefully felt their way; two crutches are absolutely necessary at first, and one must be taken away at a time, lest too much weight should be thrown upon the leg at once.—*Lancet*.

## THE FORMATION OF CENTRAL PYRAMIDAL CATARACT.

By Dr. von AMMON.

DR. VON AMMON describes the case of an unhealthy child, two years and a half old, the subject of frequent general convulsions. It held the head with the chin resting on the sternum; the eyes rotated violently; the eyelids would suddenly be opened wide, and then convulsively closed; and with this sometimes alternated a rotatory motion of the head. The iris was brown; the pupil small and eccentric, but circular. The cornea was rather lengthened, and the limit between it and the sclerotica was not well defined. Both were very white; viewed laterally, the cornea was somewhat conical. Through the narrow pupils, there projected a clear white pyramidal body into the anterior chamber. On dilating the pupils with belladonna, the projection appeared conical; the apex was very white, the base less so, and it appeared to be seated on the lens and its capsule. The child having died of convulsions, an examination of the eyes was made.

The eyes were of a more globular form than natural. At the junction of the sclerotica with the cornea, the sclerotica formed a projection, giving rise to the appearance of a circular channel. From the side, the projection through the pupil into the anterior chamber was seen; it was closely surrounded by the iris, so that the transparent part of the crystalline lens could not be seen through the pupil. Viewed from behind, the lens and capsule appeared normal; and through it were seen two dark circles, produced by the base of the pyramidal projection. The sclerotica was thicker than usual; the iris was brown; the cornea moderately thick; Descemet's membrane was clear, without folds. The pupils were not in the centre of the iris. The ciliary ligaments were broad; the ciliary bodies not quite circular: the ciliary processes were normal; the *corona ciliaris* was imperfect. The retina, rather thick, presented on its inner surface a great number of projections, some round, others long, which collapsed on being pricked with a cataract needle, and some gave exit to a clear glutinous fluid. The central vessels were normally developed on the retina and vitreous body. The yellow spot and the fold were largely developed. The crystalline lenses were rather oblong, but of normal colour, and quite transparent. Between the capsule and the edge of the lens there was, in one eye, a yellow clear ring, apparently formed by the *liquor Morgagni*; this disappeared when the capsule was opened. Somewhat off the centre of the lens were found the white, opaque, pyramidal bodies, which were very easily detached. These bodies resembled mushrooms, pointed at the top. Where each had lain on the lens, there was a slight depression; and a deeper one in the centre, where the stem of the mushroom-like body had been inserted. At this point, the capsule of the lens was absent; but whether from absorption, or from close union with the pyramidal bodies, could not be ascertained. The pyramids were composed of layers, some of which were thick, others thin, some clear, others darker. Under the microscope, a thin section of them appeared amorphous.

Dr. von Ammon has traced the commencement of this affection in several cases, both in the fœtus and in the child after birth, as a depression in the lens, arising probably from defective development. The anterior wall of the capsule is prolonged into this depression; and the cataract is probably formed by gradual deposition from the aqueous humour.—*Lond. Jour. of Med.*

This was evidently one of the cases of congenital central opacity of the capsule of the lens called *cataracta centralis* by the Germans, occurring in an oscillating eye, such as often accompanies congenital cataract. There was nothing unusual in it, and the elaborate report of the dissection only tells that the eye was otherwise free from defect.

## HYDROPHOBIA TREATED WITH CHLOROFORM.

By Dr. SANDWITH of Beverley.

WHETHER chloroform will prove to be an antidote for hydrophobia remains to be seen, and is an event rather to be desired than expected; but that it will procure an euthanasia is certain. In order to prevent speedy death from the exhausting effects of the spasms of the throat, and allow time for the elimination of the morbid poison in hydrophobia, it has been proposed to open the trachea. It would, however, appear from the following case that all the advantages that could be derived from tracheotomy may be obtained from chloroform, and these in a manner far more agreeable to the patient as well as the medical attendant.

Wm. Warden, aged 42, was attacked by a strange dog, and one of the fingers of the left hand was wounded, about six months prior to the outbreak of the symptoms of hydrophobia. The dog was immediately destroyed, and the wound healed so quickly that in the course of two or three days he was able to resume his occupation as a labourer in a tan yard. On the 4th of October he applied to one of the medical officers of the dispensary, on account of a pain in the left side, which was supposed to be rheumatic, and was treated accordingly. In the evening of that day symptoms of hydrophobia made their appearance, and the following morning he was visited by another medical man, who bled him from the arm to a moderate extent. The paroxysms increasing in frequency and violence during the day, in his struggles the bandage became loose, and he lost a very large quantity of blood. By this untoward event, and the exhaustion produced by his struggles to recover his breath, when nearly strangled by the spasmodic contractions of the muscles of the larynx, his strength was greatly reduced. His struggles during a paroxysm were said to be terrific, and it required the strength of four men to keep him down in bed.

Through the kindness of Mr. Brandon, jun., I saw this patient at eight o'clock p.m., and remained at his bedside some hours. He was raving like a maniac, and was in a state of extreme debility. The face was pale, and the skin covered with a cold clammy perspiration; the pupils of the eyes completely dilated; the corners of the mouth retracted; the breathing hurried; the pulse 120 in a minute, thready and vermicular; and the paroxysms produced by the spasms of the throat terrible to behold. The head was on these occasions drawn backward, and he made the most vehement efforts to get out of bed, foam issuing from his mouth profusely.

Some chloroform had been administered during the afternoon. I recommended it to be repeated, and had the satisfaction of witnessing its effects, which were almost magical. He was no sooner under the influence of this potent spell than his respiration became perfectly tranquil; some colour returned to his cheeks; the pupils contracted; the pulse became calm, and, considering his weak state, well developed, the number of pulsations in a minute not exceeding 84; and he lay in a state of happy delirium. A more pleasing transition from extreme agony to tranquil ease I never witnessed before. The effect of the remedy was maintained during the night by the occasional use of small doses; but he died the following morning, without pain or agony.

It must be admitted that this was not a favourable case to test the power of chloroform as an antidote. The unhappy patient had lost so much blood as almost to induce me to believe that his death must be set to the account of phlebotomy, rather than to hydrophobia. But on the supposition that we are not yet in possession of a specific for this frightful malady, which is too probable, it must be a gratification to every humane mind to know that it is in our power to alleviate the dreadful sufferings peculiar to hydrophobia, and render the last hours of an unhappy patient tranquil, and free from pain.

In the case of hydrophobia related by Mr. Hunter, he says:—"The pulse in the beginning was not quick, nor was the skin hot, and there was none of the muscular debility so remarkable in fever;" and Dr. Currie of Liver-

pool, who saw five cases, says: "In none was there any sense of animal heat." It is clear, therefore, that the disease is not inflammatory, and bloodletting is contraindicated. There appears, indeed, to be an affinity between this disease and its congeners—hysteria, mania, and tetanus, in none of which is there an increase of animal heat. Galen calls mania the "delirium sine febre;" and according to Dr. Beddoes "it is certain that tetanus exists without increased heat;" which conclusion is supported by the experiments of Dr. Currie, whose remarks on the impropriety of bloodletting in tetanus are equally applicable in hydrophobia. "It is deeply to be lamented," says this able pathologist, "that this disease should ever have been considered as of an inflammatory nature, and that there are even now physicians who treat it by venesection. It is in my mind decisive against this supposition that though the general system is so powerfully affected, the animal heat is not increased, which it uniformly is in all cases where there is an inflammatory affection of the system, whether originating or terminating in local phlegmonic inflammation."

Opium has always failed to give relief in hydrophobia; and I cannot think favourably of large doses of arsenic, as recommended by Dr. Billing. We may, however, hope that as we have obtained a remedy for the painful symptoms of this distressing malady, an antidote will yet be discovered. An eternal debt of gratitude is due to Doctor Simpson for his discovery of the anæsthetic properties of chloroform, which, if administered, with the cautions and restrictions laid down by Mr. Nunneley of Leeds, can seldom be dangerous.—*Prov. Med. Jour.*

## CASES OF SCIATICA AND NEURALGIA SUCCESSFULLY TREATED BY ACUPUNCTURE.

By H. S. BELCOMBE, M.D.,

Senior Physician to the York County Hospital.

UPON these cases, Dr. Belcombe makes the following observations:—

As magnetism, galvanism, and the phenomena relating thereto, and its effects upon the human system, seem at present special objects of research, I take the liberty of submitting a few cases of painful disease, where the success of the treatment, to my mind, was principally due to the use of a remedy by no means old in this country, and received with much favour when first introduced by Dr. Elliotson, but which seems now to have fallen into disuse, at least I never hear it proposed in consultation, and the last edition of Dr. Watson's lectures, which I understand is a text-book both in London and Edinburgh, makes no allusion to acupuncture, except for the relief of anæsthetic swellings. I must premise that there has been much rheumatism and neuralgia in this part of the world, but I have reason to believe that I am the only practitioner who has directed the employment of the remedy. Without further preface I proceed to a plain narration.

*Case 1.*—A lady of fortune, æt. 65, stout, full habit, partial to luxurious living, but a water drinker, indolent as to exercise, except in a carriage, was attacked early in the spring with severe pain across the loins, shooting down the thighs, causing great inconvenience night and day. The bowels were confined; urine moderate in quantity, turbid. The means used gave very partial relief; presently the pain centred just between the tuber ischii and trochanter major, darting down to the knee and ankle; spasmodic action of the calf of the leg, sometimes very great. A needle was inserted just at the seat of pain to some depth, and another two inches lower in the same direction. Both were kept in for two hours and then withdrawn; the pain entirely subsided, and has not hitherto returned.

*Case 2.*—A retired tradesman, æt. 70; very corpulent; moderately active; fond of the pleasures of the table, but sober. Symptoms much the same, only the pains resembled more the neuralgic tic, and rest was impossible. The needles were introduced three different times before success was obtained; but when obtained it was complete.

*Case 3.*—A butcher, middle-aged, tall, stout, plethoric;

very active in his pursuits, very moderate in his diet. The pains first commenced in the loins, then the shooting down the thighs, preventing his going to market or attending in his shop; then they concentrated in the sciatic nerve. The needles completely relieved the pain after one insertion.

*Case 4.*—A married lady, in easy circumstances, æt. 45; no family; very active in her mode of life, very temperate in her living, yet inclined to corpulency; for two years she had been seldom free from this vexatious sciatica, rendering her existence very uncomfortable. Many measures had been tried in vain for relief, and it was only by the effect of persuasion she was induced to consult me. The insertion of the needles was attended with complete success; the pains have not hitherto returned, and her movements are as free and easy as in youth.

I might add three more cases, where the disease was situated in the nerve of the upper extremity, though the effects were most sensibly felt in the wrist, the pain in the shoulder being only casually mentioned or thought of. The insertion of the needles has been always successful. In these belladonna plasters were also applied to the wrists, though more I think to gratify the patients, who were resolute the seat of disease was there, than from any expectancy I had of relief, though in many cases I have full confidence in the remedy. One case I may mention. A countryman had a paralytic seizure two years back, which deprived him of the power of speech, though the limbs perfectly recovered. I was sent for lately early in the morning. I found him incapable of using his right arm, which seemed to hang motionless, and his friends were persuaded he had had a paralytic attack in the night. From learning somewhat of the history, and examining attentively the limb, observing there was a more clonic spasm than paralytic degeneration, I was certain it was rheumatism, and had a belladonna plaster placed upon the shoulder and muscles of the neck. Other medicines, I think, were calomel and opium. The intelligent countenance, the clear eye, following me attentively as I made my examination, strengthened my judgment as to the nature of the attack. He recovered very shortly. The medicines I gave in all the cases of sciatic lumbago were acetate of potash in compound infusion of senna, the patients finding much relief from the movement of the lower bowels, and pressure being taken off the kidneys. In the neuralgia of the upper extremity carbonate of iron in full dose was given.

The different medicines were given with a view of testing their peculiar operation. I am of opinion that full purgation is very useful in all cases of rheumatism, especially in the acute; and that it is more useful where the lower extremities are attacked than when the distress falls upon the upper. The carbonate of iron is certainly an excellent remedy where the chronic form prevails. Many years since, I had an epistolary controversy with a Stafford physician on the subject, which appeared in the medical periodicals of those bygone days; but, as he answered not my last letter, I claimed to myself the victory, as remaining on the field; and the practice I have pursued has only corroborated my judgment. The *ratio medendi* I have nothing to do with; I have only to observe, that sound physiology will always lead to proper modes of practice, whereas theoretical ideas will lead to very unsafe conclusions. My meaning may be thus expressed in other words: There is often a condition of the system which may appear inflammatory, it is only irritative: apply depletory measures, you increase it; waiting awhile, and observing that inflammation does not increase—for it is its sure character to proceed—you may then trust to your more nervine, or, if you please, tonic remedies. Assuredly there are remedies well adapted for the relief of most disorders which affect our system; how to apply, when to apply, is the wisdom of medicine.

Dr. McCulloch wrote two large volumes to prove that malaria was the cause of all neuralgic diseases. I have read them attentively—have observed, I hope, accurately, but I cannot agree with him. I think much of this disease may arise from mode of life, variations of temperature,

internally and externally; sudden changes, such as we have experienced lately. At all events, the cases I have narrated were neither in confined situations nor subjected to such localities, and they were all isolated, that is to say individual—I had not two cases in the same locality, nor were any of them near the Foss, which is a condemned quarter of our city—unjustly, to my mind; for the hospital is near to it, good houses are built and building in its vicinity; nor am I aware of any of the peculiar diseases of malaria particularly noted there.—*Med. Times and Gaz.*

## INDIAN HEMP AS AN OXYTOMIC.

By JOHN GRIGOR, M.D., Nairn.

At the meeting of the Edinburgh Obstetrical Society, July, 1850, Dr. Simpson stated that "he had been induced to try the effects, if any, of Indian hemp, during labour, in consequence of Dr. Churchill stating that it possessed powers similar to those of ergot of rye in arresting hæmorrhage, when dependent upon congested states of the unimpregnated uterus. In the few cases of labour in which it was tried, parturient action seemed to be very markedly and directly increased after the exhibition of the hemp, but that far more extensive and careful experiments would be required, before a definite opinion could be arrived at relative to its possession of oxytomic powers, and their amount."

In the last August number of the *Monthly Journal of Medical Science*, there is an article, by Dr. A. Christison, on the parturient effects of Indian hemp, being a continuation of a previous one on the natural history, &c., of that medicine. These remarks are, so far as I know, the first and last that have been given birth to on that peculiar, and as I think uncertain, effect of the *Cannabis Indica*. I could have wished that these observations had been made on a more extended scale, and the effects more particularly and individually noticed, yet I will hope that my evidence may induce some others of my brethren to try it and note its effects, so that from step to step we may at length attain a full and correct knowledge of its powers and defects as a promoter of the labour pain.

Since reading Dr. Christison's seven cases, conducted at the Maternity Hospital of Edinburgh, I have used the Tinct. *Cannabis Indicæ* (24 grs. ext. to 3j.) in sixteen cases. In nine of these, though given to the extent of 5j. ss. in separate doses of 25 and 35 drops at a time—in some in quick succession, in others at longer intervals—I could not perceive any increased uterine action, nor the slightest physiological change in any one way during labour or afterwards, with the exception of one instance of sleep (much required at the time) in a lady, far from strong, confined of her third child, and much exhausted by inefficient throes, in whom the third 5ss. dose completely arrested the pains and induced sleep, which continued for an hour, when she awakened refreshed. Labour then set in in earnest, chloroform was given, and the child was speedily born. These nine cases made good recoveries.

In the seven cases in which the tincture of hemp succeeded so well with me, five were cases of first confinement, of satisfactory though very slow labour, and phlegmatic temperament. I have noticed the contractions acquire great increase of strength and frequency immediately on swallowing the drug, and have seen four or five minutes elapse ere the effect ensued; and if none was induced within the latter space of time, I have not observed its effects at all afterwards, notwithstanding repeated doses. In these few cases, I had opportunities of giving it from the time when the os uteri would admit the point of my finger till the expulsion of the child. Judging from experience, I believe that, in appropriate cases for the use of this stimulant, and when effectual, it is capable of bringing the labour to a happy conclusion considerably within a half of the time that would otherwise have been required, thus saving protracted suffering to the patient, and the time of the practitioner.

I have not observed it to possess any anæsthetic effects. I have used it in two cases along with the inhalation of

chloroform, and I did not observe that that agent interfered in any way with its action. When the effects of the hemp were subsiding, I have been able to recal and keep up the "good pains" by the addition of ten drops given from time to time. I consider the expulsive action of the cannabis to be stronger than that of the ergot, but less certain in its effect; and it has the advantage over the ergot, of usefulness in the early stage of parturition. I believe that the previous ineffectual administration of the hemp does not interfere with the after-exhibition and full working of the ergot.

Such are my brief observations on the new and interesting use to which Bang, or the Hachisch of India, has been put. In the few cases in which I thought its administration safe, and not counter-indicated by malformation, &c., you have given the result of those in which this effect was and was not displayed. I cannot conclude these remarks without entering my dissent against the use of uterine medicinal stimuli in general, on account of the frequent difficulty of accurate conception of relative dimensions of parts, &c. Yet all obstetricians must acknowledge that, in many cases, such stimuli are indispensable; and to be possessed of one capable of so early application, is decidedly a matter of much importance. I would also notice that, in labour, whether the cannabis shows its peculiar effect on the uterine contractions or not, there seems, as in tetanus, &c., to be a very great tolerance of the drug—nor have unpleasant consequences, so far as I have seen, appeared afterwards; and whilst it is acknowledged as a powerful controller of inordinate muscular spasm, it is equally, in many cases, a powerful stimulant of the uterine muscular fibre in labour, if not in the unimpregnated state.—*Monthly Jour.*

### ON CONGENITAL AND HEREDITARY EPICANTHUS.

By Dr. SICHEL.

CONGENITAL epicanthus is noticed by Dr. Sichel to frequently accompany that abnormal configuration, which is characterised by flattened and wide nasal bones. In these cases, the integument, instead of being stretched evenly between the root of the nose and the inner commissure of the eyelids, forms a semilunar fold directed from above downwards, with the concavity looking outwards and towards the eyeball. It sometimes extends from the inner third of the upper eyelid to the junction of the inner with the middle third of the lower one, covering in the caruncula lachrymalis, and a great part of the sclerotica; sometimes it commences less superficially, at a greater distance from the eyebrow, yet so that it is not shorter, but only narrower. In the latter case it may be readily overlooked. The effects vary according to the degree. The fully developed form gives rise to a peculiar disagreeable expression of countenance, reminding one of the Mongolian race. There is difficulty in opening the eyelids; and lateral vision is much impeded, the eye being often partially covered when the patient looks inwards. The puncta lachrymalia generally occupy their normal position.

The deformity is congenital, and is usually present on both sides. Dr. Sichel regards it as resulting from a development of the integument, disproportionate to the size of the nasal bones which support it. He has arrived at the conclusion that it is connected with flattened nasal bones, and that it may be considered as transitional between the Caucasian and Mongolian races, from an examination of the Iowa Indians, some time ago exhibited in Paris. The following points connected with the subject are interesting, but require to be determined by accurate data. 1. Does epicanthus become more frequent as we advance eastward; i.e., among the Mongolians than among the Caucasians? 2. The more aquiline the nose is, the less likely is epicanthus to occur; and Dr. Sichel has never found it in persons of the Jewish race. 3. It decreases from north to south; especially in Spain, where the European and the Asiatic blood of the Caucasian race has been intermixed.

The deformity may be hereditary. Dr. Sichel saw a gentleman with epicanthus, who had five sons and one

daughter all similarly affected, while one son and four daughters were free from the deformity. One of the sons had a daughter, who also had epicanthus.

Epicanthus is sometimes imperfect, there being a mere trace of it on one or both sides. It is not of much importance, not impeding the motion of the eyelids, nor producing deformity properly so called. Single epicanthus is very rare, and may be regarded rather as a species of imperfect double epicanthus, the rudimentary form of the disease being present on the other side, and the nasal bones possessing the peculiar conformation.

The treatment consists in raising a pinch of skin at the root of the nose, and excising it. The edges of the wound are brought together, and by this means the folds are obliterated. The most common complications of epicanthus are ptosis and convergent strabismus; erosion of the abnormal fold from the tears and irritating secretion may also occur, and a kind of entropium may sometimes attend the deformity.—*Lond. Jour. of Med.*

This is a natural defect, amounting to such deformity that it may often be called a congenital malformation; yet were it not from its peculiar effect on the countenance, it might pass observation, as many queer features do. We are somewhat sceptical as to the uniform success of an operation.

### ON THE CATARRHAL PNEUMONIA AND LOBAR PNEUMONIA OF CHILDREN.

By MM. TROUSSEAU and LASEGUE.

CATARRHAL (or lobular) pneumonia is a disease as distinct from simple (lobar) as variola is from erythema. This is seen in their respective mortality. Of twenty children who have been admitted into the hospital clinique suffering from simple pneumonia, in six months all have recovered; of nearly thirty who were attacked with catarrhal pneumonia, not one survived. Most of the first class of cases exhibited an excessive degree of acuteness, which burnt out like a fire of straw; while several of the second, notwithstanding their fatal termination, commenced with very mild symptoms.

Simple pneumonia hardly ever affects a child below two years of age, and rarely those of two or three, but becomes of more and more frequent occurrence as the child approaches adolescence. Its cause and symptoms resemble those of the adult, with some modifications. After twenty-four or thirty-six hours, the souffle and bronchophony can alone be heard; the crepitant râle, which is often observed in the adult when the patient coughs, even when much souffle is present, is hardly ever heard in the child. So afterwards, from day to day, without the crepitation of resolution, the souffle disappears, leaving only a feeble respiration. The progress of the disease is also more rapid than in the adult. In the mild form of the disease, recovery takes place rapidly, and in large proportion; but in its grave form, many cases are lost by any mode of treatment. M. Trousseau generally bleeds the child, gives it an emetic of sulphate of copper, and then a mixture containing Kerme's mineral and extract of digitalis.

Catarrhal pneumonia commences with a catarrh, which rapidly extends to the small bronchi, and then we hear numerous and small subcrepitant râles disseminated over both lungs, and especially posteriorly. These râles may persist for four, six, eight, or fifteen days, without any souffle becoming manifest; but sooner or later we hear a souffle, the resonance of the cries or the voice, or at least a prolonged respiratory murmur. While these latter sounds, common to simple and catarrhal pneumonia, are thus manifesting themselves, we find by the subcrepitant râles that the capillary catarrh is still persisting in the rest of the lung. The disease has extended from the mucous membrane to the parenchyma of the organ. Febrile action is less than in ordinary pneumonia, being predominant at some portions of the day and entirely ceasing at others; and these alternations of better and worse may continue for fifteen, twenty, or thirty days; the disease being origin-

ally a pulmonary catarrh, and partaking of the obstinacy and uncertainty of catarrhal complaints. As more and more of the parenchyma becomes implicated, the fever becomes more continuous and intense, and the respiration more difficult, until the children die exhausted. In other cases, in which the bronchial phlegmasia was very intense from the first, and the lung became rapidly invaded over a great extent, death takes place with rapidity. The progress of the disease has usually been more rapidly fatal when it has succeeded to measles, chronic disease of the skin, or laryngitis. All means of treatment that have been tried have proved impotent.

These two affections may be compared, *exceptis excipien- dis*, with erysipelas and phlegmon. Erysipelas traverses the surface, like the catarrh; and when it persists too long, it induces ulcerations of the skin, furuncles, and circumscribed subcutaneous abscess, just as the capillary catarrh induces suppuration of the lobules, little abscesses of the lungs, and circumscribed pneumonias. Simple pneumonia, on the other hand, progresses like simple phlegmon, violent in its febrile reaction, but terminating abruptly and rapidly.

It must not be supposed, from what has been said, that catarrhal pneumonia is almost invariably fatal. Although this is the case amidst the miasmata of an hospital, which exert effects at once so terrible and so difficult to avert, it is not so in private practice. In this, one-half the patients may be cured by repeated vomiting, flying blisters, antimonials, and digitalis; but how terrible are the ravages of a disease which, under the most favourable circumstances, kills one-half its subjects!—*Brit. and For. Med. Chir. Rev.*

#### SENILE GANGRENE TREATED BY LOCAL BLEEDING.

By Mr. COWLEY of Winslow.

ON Monday, May 17, 1852, I (being in the 74th year of my age) was attacked with an uneasy sensation in the second toe of my right foot, occasionally paining me like the sting of a nettle. Upon examination, the whole of the toe, to the first metatarsal joint, appeared of a red and inflamed colour, slightly tender to the touch, and somewhat enlarged. An application of diluted tincture of iodine produced no sensible effect. A second dressing of the same was applied on the 18th. On the 20th, the whole toe was considerably enlarged, vesication had taken place all along its dorsum, and the colour of the toe was assuming a dark purple hue. The iodine was discontinued, and ceratum album with a spirituous lotion were substituted, with the use of Markwick's epithem, until the 23rd, when the fourth and fifth toes became inflamed like unto the second, at its commencement, with a slight swelling without pain, but some irritation. From the fatal results I had witnessed of various cases during an apprenticeship and practice of fifty-nine years, and which cases had commenced in a similar manner to my own, I felt convinced (as no injury had been inflicted) that the disease was "senile mortification," and at once resolved to deviate from the long-continued practice of trusting for a cure to the use of cataplasms, opium, &c. (which rarely arrested the disease in its incipient stage, and seldom succeeded after sphacelus had taken place), by trying the effect of local bloodletting. I therefore extracted eight ounces and two drachms of blood from the saphena minor vein immediately below the ankle-joint. The direct beneficial effect produced was truly surprising; the redness of the fourth and fifth toes was almost removed, and the dark shining appearance of the second considerably improved in colour, and the swelling diminished. The same dressings were continued till the 28th, when a relapse took place, the fourth and fifth toes became inflamed to an equal extent with the third, the second toe was also increased in size, and the colour darker; also the great toe showed decided signs that the disease was spreading to that part of the foot. I again took away eight ounces of blood, and this from the saphena major vein, situated over the middle of the first metatarsal bone. A similar result to the first bleeding was shown, the same

mode of dressings was continued to the 2nd of June, when all the symptoms of the disease recurred, but not in so aggravated a degree. Five more ounces of blood were extracted from the same vein, three inches above the ankle-joint, with equally good effect, making a total loss of twenty ounces of blood from the foot in the space of ten days.

The inflamed parts were now dressed with spt. terebinthinæ, previous to the application of white cerate and epithem, but not agreeing, a common bread-and-water poultice was tried. However, not finding any material alteration, the cataplasma fermenti, P.L., was the next remedy on the 12th of June, which was continued for six days with advantage, when, although no ulceration existed, the ung. resinæ was applied over the surface of the whole foot as a warm dressing, up to the present time; and now I hope a permanent cure is effected.

During the first fortnight of the above period, the saline mixture with the volatile alkali were freely taken, and since then quin. sulph. gr. v., bis die. Port wine and spirituous stimuli have been continued to this day, without increasing the number of pulsations beyond 66, and that only in the afternoon occasionally. Although particularly enjoined by my medical friends to adopt positive and constant rest to my foot, I have persisted in the use of a leg rest and exercise in a garden chair; my general health being very good, I considered fresh air and exercise essential to its maintenance.—*Prov. Med. Jour.*

#### ON THE FINAL CAUSE OF MENSTRUATION.

By Dr. F. H. RAMSBOTHAM.

If it is really the case, of which there seems to be no doubt, that at each menstrual period in the human female the fimbriated extremity of one or both of the Fallopian tubes embraces an ovary, and causes a Graafian vesicle to burst and shed its contents into the canal, it would naturally be inferred that the formation of this fluid is subservient to the departure of the ovule from its ovarian bed, and designed to perform some important function in relation to its escape. Now, it would appear probable that the function is identical with the nutrition of the young ovum, and that the menstrual discharge, indeed, is nothing less than the rudiments of the deciduous membrane itself; or rather that it would have become the deciduous membrane, provided conception had occurred. And I think the identity of these two products is established by the following considerations.

An ovule ripe for impregnation, parts from the nest in which it had been elaborated, being conveyed by the grasp of the Fallopian fimbriæ. At the same time, Nature establishes an action for the purpose of preserving it, provided an opportunity of becoming impregnated by contact with the male semen is afforded it. Should that contact take place, and conception follow, the fluid formed is retained within the uterus, and is gradually converted into the deciduous membrane, which becomes the first medium of communication between the newly animated ovum and the maternal vessels. If, on the contrary, conception does not happen, the ovule perishes, and the fluid secreted for its advantage, not being required, is allowed to exude externally, as a superabundant and useless secretion.

This supposition, indeed, would require us to believe that the ovule may be impregnated, as well in the Fallopian tube, after its escape from the ovary, as in the ovarian bed itself; and I can discover no difficulty in believing that such should be the case. In the genus *aves*, for example, the eggs are impregnated after they have escaped from the ovary, and in that of *pisces* the same takes place, not only after they have parted from the ovary, but even after they have been expelled from the body of the parent altogether; so also in some *amphibia*, as in *frogs*.

The variation in regard to the time that elapses between conception and the commencement of labour, observable not only in different women, but also in the same woman on different occasions, may perhaps be accounted for by the part of the Fallopian tube at which the ovule becomes

impregnated; the nearer to the uterus the ovum was, the shorter the time probably that would elapse before it arrived at the uterine cavity; the nearer to the fimbriæ, the longer would be the time, because it would have a larger portion of the Fallopian tube to traverse. The period of utero-gestation, properly so called, that is, the length of time the ovum remains within the uterine cavity, is, in my estimation, definite; while the time of transit through the tube varies considerably, after impregnation has been effected; and this variation will be sufficient to explain the difference above alluded to.

The view which I have taken of this question is strengthened by the facts, that the menstuous fluid and the decidua membrane seem both to be formed by the same tubular glands lately discovered in the uterine substance—that the decidua when first formed is of the consistence of a viscid fluid—that in dysmenorrhœa a membrane is not unfrequently formed within the virgin uterus, which has very much the external characters of the decidua, and indeed can sometimes scarcely be distinguished from that membrane, the result of impregnation—that those females who menstruate irregularly or painfully are not so obnoxious to pregnancy as those in whom the function is normally performed—that the catamenia will sometimes appear once soon after impregnation, as though more fluid had been afforded than was required for the purposes intended—and especially that, as in the lower animal, no deciduous membrane is formed, therefore there is no necessity for any menstrual secretion; and we know that woman is the only animal subject to this peculiarity.

The position, then, deducible from the foregoing observations is, not only that whenever impregnation occurs, a secretion is elaborated by the uterus for the purpose of affording nourishment to the ovum, but that, independently of conception taking place, an ovule, even in the virgin, passes periodically from the ovarium into the Fallopian tube, and at the same time the same provision is made by Nature for its preservation, in anticipation of its becoming vivified; but that if this vivification is not effected, the fluid formed flows away, is cast off, indeed, as effete matter, and is what we popularly call the menstuous discharge.

The periodical return of the discharge cannot be considered as militating against this theory, but rather as supporting it; not only because we have constantly before our eyes instances of functions in the body performed with periodical exactness, but also because we know that in those of our graminivora which bring forth but once annually, the season of conception is so determined that the young should be produced in the spring. Thus the mare and the ass, whose period of gestation is eleven calendar months, conceive almost immediately after parturition—the mare on the ninth day after, the ass on the seventh—to the evident intent that a new progeny may be reared in the summer months. The cow, whose period is nine months, does not, however, conceive till three months after her last birth. The sheep and goat, which carry their young five months, will not take the male till the end of autumn; and the hare, whose term is only thirty days, does not become impregnated until eleven months have passed since the last parturition. This extreme variation in these different races of animals is evidently instituted with one single object—namely, that the young may be produced into the world at that season of the year most favourable for their nurture. And if Nature has been so precise in regard to the lower animals, we cannot wonder that she has displayed an adherence to a similar system in the case of the females of our own species, or that there should exist in the human subject the same kind of periodicity in regard to the perfection and escape of the ovule from the ovarium.

Nor can the waste which such a frequent loss of the ovule must entail on Nature, be regarded as an objection, since we see, as well in the animal as in the vegetable kingdom, loss to an enormous amount, exactly of the same description, constantly going on. How few seeds, comparatively, even after fecundation, become productive, and what

a wholesale destruction of organic life is there not witnessed in the case of fishes. Of the million, or the million and a half of ova expelled from the ovarium of the sturgeon, for instance, how few are fecundated, and how few of those that are fecundated survive to be elevated into the existence of a living independent animal. If Nature permits such a waste to be inflicted on her, in the reproduction of one genus of animals, we cannot surely find difficulty in believing that the same prodigality (so to speak) may in a minor degree influence her operations in the human subject. —*Braithwaite's Retrospect.*

## CASE OF SATURNINE PTYALISM.

By H. HILL, M.R.C.S.L.,  
Bytown, C. W.

THE following instance of a peculiar idiosyncrasy, or susceptibility of the constitution to the effects of lead on the salivary apparatus, may prove interesting to the pharmacist as well as to the toxicologist. During the past spring I was in attendance on a lady who was threatened with miscarriage about the eighth week of pregnancy. The symptoms were very slight at first, being confined to the smallest possible appearance of hæmorrhage, unattended with any pain or sense of weight in the pelvic region; it consequently was thought, that by enjoying rest in the horizontal position with the use of sulphuric acid and opium, that all unpleasant consequences would be avoided. After having kept the patient in bed for a fortnight, during which time there were occasionally the very slightest marks of hæmorrhage, one morning the sign of abortion became too evident to be any longer mistaken, or the expectation of its recurrence to be further delayed; after a few hours the ovum became detached and came away, with considerable flooding at the time, and continuing for days and weeks afterwards. It was soon after the continuation of the hæmorrhage that I commenced to administer the acetate of lead in five-grain doses with ergot of rye, about every four hours; its effect on the flooding was marked; the discharge became decidedly lessened, but on the third day all the symptoms of mercurial salivation were evident, the gums were much swollen, the buccal and labial glands elevated and raised, the sublingual and submaxillary glands enlarged and painful, whilst the saliva was pouring from the mouth, possessing the characteristic fetor of ptyalism. I should have sought the explanation of these phenomena in an accidental admixture of calomel or corrosive sublimate in the specimen of lead, of which I was availing myself, had it not been for the circumstance, that, about two years previously, under precisely similar conditions with the same individual, like results had taken place; at that period, having been using portions of the same specimen of lead in several cases without any of these abnormal effects, I had no reason for suspecting its purity; but in the latter instance, I examined it with hydriodate of potassa, which only threw down the beautiful yellow precipitate of iodide of lead, without any vestige of the salmon colour of iodide of mercury. So singular an effect of lead I have never before met with, either in practice or in the works on *metieria medica*, or toxicology; on the contrary, in Christison's work there is reference made to a paper published by a Mr. Daniell, in the London "Medical Repository," advocating its use as a remedy in mercurial salivation.

This unfortunate idiosyncrasy existing in my patient, effectually excluded the continuance of the acetate, which was immediately followed up by a return of very distressing hæmorrhage, and was only finally controlled by the use of the tampon, which I look upon as a most effectual means of arresting uterine hæmorrhage, and one that is too seldom had recourse to from non-appreciation of its utility, or from prejudices founded on its unphilosophical effect of rather assisting to distend the uterus, than of allowing of its permanent contraction, and plugging up the vessels by coagulation of the blood — *Canada Medical Journal.*

## TREATMENT OF OPHTHALMIA BY OCCLUSION OF THE EYELIDS.

M. FORGET, after passing in review the different means used in the treatment of ophthalmia, directs particular attention to the use of cold applications, and occlusion of the eyelids. The use of cold water he believes to be beneficial in almost all cases of ophthalmia. The application must be permanent, frequently renewed, and continued until the symptoms have completely disappeared. The addition of vinegar, acetate of lead, alum, &c., is almost useless. He has seen good effects result from this treatment in cases of simple injection, in severe inflammation pain, photophobia, and even in ophthalmic blennorrhœa. Even in cases where topical applications are ill born—in ophthalmia with relaxation of the tissues—the employment of cold water may still be useful. This remedy necessitates occlusion of the eyelids; and M. Forget doubts whether the benefit is not really owing to this circumstance. In many cases simple occlusion is sufficient, but cold applications are an useful adjunct where there is much redness, heat, pain, and swelling. The advantages of occlusion are, that the organ is kept in a state of repose, protected not only from light, but from the air and from foreign bodies; that the eye is maintained in a state of equable moist heat; and that the eyelids are made to exercise a mild, equal, permanent, *natural* compression on the inflamed parts. M. Forget relates some cases of severe ophthalmia, in which occlusion was tried with marked benefit, sometimes after the usual remedies had been employed without effect. It is sufficient to keep only the affected eye closed; a bandage is the best means. In cases of rheumatic, scrofulous, or other specific forms of ophthalmia, other means may also be necessary. When there is much muco-purulent secretion, it will be necessary to cleanse the eye carefully.—*Lond. Jr. of Med.*

This is the treatment so generally adopted by old women and young surgeons of the blue-stone and green-shade school in Ireland, and which blinds so many poor children. It is scarcely necessary to warn our readers to avoid carefully every approach to such mischievous and absurd practice.

## SORBINE.

*A New Saccharine Matter obtained from the Berries of the Mountain Ash (Sorbus aucuparia).*

By M. PELOUZE.

THE berries of the mountain ash, collected about the end of the month of September, were bruised and pressed in a cloth. The juice thus obtained was left to stand in earthen vessels for thirteen or fourteen months. During this time deposits and vegetations were repeatedly formed, but these were not submitted to examination. The liquor, which underwent spontaneous clarification, was decanted, then evaporated at a gentle heat to the consistence of a thick syrup. This syrup deposited crystals of a brown colour, which after being twice treated with animal charcoal, were obtained colourless. Further quantities of the same substance were procured by successive concentrations of the remaining syrup, and these were purified with as much facility as the preceding.

Three analyses of the sorbine, made with the greatest care on perfectly white and transparent specimens, the combustion of which left no trace of residue, proved beyond a doubt that this substance contains an equal number of atoms of carbon, hydrogen, and oxygen.

Sorbine is colourless, having a decidedly saccharine taste, which cannot be distinguished from that of cane-sugar. The crystals are perfectly transparent, hard breaking between the teeth like sugar-candy. The specific gravity of the crystals is 1.654. Water dissolves about twice its weight of it. Boiling alcohol, on the other hand, dissolves but a very small quantity, which is deposited again on cooling, in the form of octahedrons similar to those deposited from an aqueous solution. A concentrated solution of sorbine resembles a syrup of common sugar. Its density, determined with a solution which was not quite pure, was 1.372 at 60 deg. F. The sorbine, and the syrup which it forms with water, are therefore both a little more dense than cane-sugar and its solution.—*Phar. Jour.*

## MEDICAL PRESS.

“SALUS POPULI SUPREMA LEX.”

DUBLIN: WEDNESDAY, SEPTEMBER 8, 1852.

## PAYMENT FOR MEDICAL SERVICES.

WE rejoice to hear in all quarters the same expression of determination to reform the system which obliges Medical Practitioners to give their professional services without payment. It is, in fact, one of the many evils which are now curing themselves; and although the cure may be slow, it will be a certain one. In the article we copy below, the complaint is touching the metropolitan Hospitals, but it applies much more to provincial Institutions, and to the public service generally, if not to private practice also. That the metropolitan Physicians and Surgeons seriously injure their provincial brethren by their free tender of gratuitous services, both in public and private, there can be no doubt; for by so doing they establish a precedent which is every day quoted against the “Country Doctor”:

The entire hospital arrangements, in all that relates to medical men in this metropolis, requires revision; but we are glad to see such unmistakable signs of the interest excited on the subject of “gratis hospital work.” It shall not be our fault if this important subject is suffered to go to sleep for another generation. The wrong inherent in the present system of non-remuneration, or remuneration by a beggar's dole, and its meanness towards hospital medical men, we have already insisted on. But though the evil begins by the injury done to hospital medical officers, it by no means ends there. It would be difficult to say what class is most deteriorated by the present method: the hospital men themselves, the students, or the profession at large. The hospital officers are injured by having to work most laboriously without any direct remuneration. Every temptation is held out by governors for making hospitals merely the means to gain the end of professional practice—namely, income and repute. If patients are well cared for, it is in spite of the present system, rather than by any encouragement it holds out to professional men. As regards students, we have shown that they are made to pay medical officers, instead of the governors; and our entire system of medical education is a still more direct machinery for paying those salaries which governors and boards withhold, than it is for the purposes of sound medical education. By a pecuniary levy in the shape of exorbitant lecture fees, medical students are made to do great part of the work of charity, in paying medical men; and in some institutions they even contribute by these fees to maintain the beds in which the patients whose cases are to instruct them are lying. Young men, dressers, house-surgeons, clinical clerks, registrars, and other working students, not only pay exorbitantly, but really slave in the service of our great hospitals. Students are made to pay in every direction, and to work in every direction; while those who know anything of the economy of our general hospitals, know that they could not go on without the work of the over-taxed students. We are not contending that students should not pay for the means of instruction; but, according to the present system, they pay, not only for their instruction, but they pay indirectly the medical officers, who should be paid by the governors. Take St. George's, for instance, one of the richest of the voluntary hospitals: we believe the surgical pupil pays £52 10s. for perpetual hospital attendance—half as much as the entire cost of the education of a barrister. Yet this student, after the first year, becomes a servant of the hospital, and works as hard in the administration of relief as the medical officers themselves. Such fees could not be thought of, did not the idea of paying medical officers by students' fees enter into the minds of those who framed the scale of payment. To the profession, the injury of such a vast system of gratis work is incalculable; it deteriorates professional character and the estimation in which medical men are held, for nothing is truer than the saying that all which can be had for nothing is undervalued. A sneer is always ready for the young professional man who during his years of struggle takes “advise gratis” for his motto; but the “advise gratis” which rules in our great hospitals passes without remark. The one is not so injurious as the

other, for the second is but a repetition of the first on a gigantic scale. What is true of the open shop or dispensary, is true of the hospital. The evil is the same; only the evil, by being more gigantic, loses something of its contemptible appearance. It is not the less hurtful, however, for being more immense. We earnestly trust that some means may be found of reforming the administration of our hospitals in all that relates to the services of medical men. Without this, hospitals, while they are great blessings, are, at the same time, great evils to the medical profession. Take the great hospital of St. Bartholomew. In certain senses, it is one of the noblest institutions in the world; but taking into consideration the fact that within its walls the work of administering to 85,000 persons per annum the medical and surgical necessities for all practical purposes, "free gratis for nothing," it is a vast engine for demoralizing the medical profession and for lowering the estimation in which medical services are held, and according to which they are paid by the public.—*Lancet*.

It is not in London only that "all that relates to medical men or hospital management requires revision." Dublin, with its seven General Hospitals, requires it still more. The subject demands something more than the partial and narrow view hitherto taken of it, and something better than the shabby policy of a cheese-paring Chancellor of the Exchequer. General Hospitals must be supported in the city for the poorer citizens and occasional population, not entitled to relief as paupers; and if so, adequate provision should be made for their medical administration. The present plan of supporting this class of medical charities by a tax levied off the citizens, a parliamentary grant, and private subscriptions, is a good one; but there is a want of system and control as well as an unequal distribution of funds, which leads to wasteful expenditure and inefficient operation. We have had enough of the miserable popularity-hunting policy, carried into operation by place-makers and place-hunters which disturbed everything and left nothing perfect or finished. It is high time to consult some other interests than those of party, sect, or political adherents, in the organization of public institutions; high time to deal with public measures on their merits, and not on considerations as to their effects on the fortunes of craving individuals. The Councils which suggested the discontinuance of the salaries of the Surgeons of County Infirmarys and the withdrawal of the Dublin Hospital Grants, fortunately no longer prevail, and an open is now left for the adoption of an honest and a wiser policy. We have had a great deal of talk and scribble about the rights of men to payment for their labours, to free trade in all commodities, and to political privileges; let us see a little practical application of these theoretical flourishes to medical workmen. "A fair day's wages for a fair day's work" are as justly due to the Hospital and Dispensary Surgeon as to any other operative employed by the State.

#### PAYMENT OF MEDICAL WITNESSES.

We often think that we are worse used in Ireland than our brethren in England, but it is often the reverse. We sometimes fare better, because we often assert our rights more effectually. Medical witnesses are badly paid in Ireland, and sometimes not paid at all; but in England they seem to have no law or rule to secure them against the arbitrary proceedings of official people. Medical men may be called on to give evidence, as other men are, in cases not arising out of professional service, and for such, of course, they should not be paid; but when called as "medical witnesses," they should be paid as every other public servant:—

I happened to be an unfortunate witness at the late Chester

assizes, and should be glad if some good could be made out of a bad matter. I live seventeen miles from Chester, and got paid seventeen shillings mileage and one guinea a day for expenses. I was obliged to stay in Chester at a hotel one day and night, as my case came on first in the morning; so I had to keep myself there, which cost me within three shillings of my allowance. I ask you whether you think a man can keep his family on three shillings a day, for I was not able to get home to do any business that day. I was talking to a medical friend from Scotland, and he had only just left Edinburgh from the assizes, and he had three guineas a day allowed him, and £5 for expenses. How is this? I should think if some petition were got up to the Home Secretary, showing the absurdity of such remuneration (if such it can be called), and signed by the medical community of England, then a more just state of things would be arrived at. Within the last five years two guineas a day have been paid to medical witnesses, who this year were sent away with one; but in medical matters, payments get worse instead of better.

Can you or any of your numerous readers furnish a table of fees to which a medical man is entitled on giving evidence in the various law and other courts, and before a committee of either house of parliament? About three months ago I was served with a summons, and paid one guinea, to attend next day and give evidence before a committee of the House of Commons respecting a water question. I attended accordingly, was examined, and was leaving the house, when I met a gentleman who holds a situation in the House of Lords. I told him my business there. He said, "Of course you got your two guineas." "No." "You are, as a professional man, entitled to that sum." I immediately sought out the attorney, who said I had been paid the usual fee. I told him I should try it in the county court. This brought him to his senses, and I was then paid.—*Letters in Lancet*.

#### TURNING "A POST" TO ACCOUNT.

We have had here in Ireland often to set our brethren on their guard against the operations of candidate placemen which aimed at the perversion of official duties to purposes of private practice, and especially against a monster attempt of the kind in the preparation of the census returns, which may not yet be abandoned. Here is an example of this kind of medical manoeuvre very properly exposed:—

Your remarks last week on the case of Mr. Jones and the Strand Union, call my attention to the unfair advantages which some surgeons (who are not over scrupulous of the manner in which they obtain practice) may take of their office as registrars of births, deaths, &c., of introducing themselves to the favourable notice of the patients of fellow practitioners. I should not have entertained suspicions of this nature, had I not been informed that a surgeon in this vicinity (Billinghurst), who is also the registrar, has acknowledged that he accepted the office of registrar from the motive of its leading on to practice. If such be the object of many surgeons holding this office, the sooner such a system is done away with the better will it be for the credit and welfare of our profession. I do not see why the office of registrar should not be generally held by the relieving officer of the district, which is the case in many places, as it would be an important addition to the salary of such a person, and would not give him a great deal of trouble, whereas to a surgeon in practice the salary can scarcely be an object.—*Letter in Lancet*.

#### MORE QUESTIONS ABOUT SHAM DIPLOMAS.

THE Medical Professors of Trinity College, Dublin, have raised a discussion they little anticipated. They thought they had nothing to do but to provide a spurious surgical diploma for the relief of needy Medical Sizzars, but they now find that others can provide spurious medical degrees to compete with their parchment. They have already brought their coals to Newcastle, and sent some of their medico-theological mustard to Durham, but they little expected a rival so far north as Aberdeen. The market they relied on may not prove so exclusively their own as they expected, for they say some of their customers there

have been "ganging sooth" before now. Sawney is a very good fellow, until Donald comes to seek a share. Of the pretensions of the rival Colleges in Aberdeen we know little: one, we believe, was founded by the Pope, and the other by the Pretender. But we shall not be surprised to see, one of these days, a board hoisted over the gate of either of them, inscribed "Scotch Logic taught, and cheap Diplomas for Army Surgeons sold, here":—

We believe that the medical degrees granted by Marischal College are utterly valueless when they are regarded as legal titles to practise. All persons who feel themselves interested in the question as to whether Marischal College is empowered by law to grant degrees in medicine, should peruse a pamphlet that has been published on the subject by the Senate of University and King's College, Aberdeen. The title of the pamphlet is as follows:—"Has Marischal College, in New Aberdeen, the Power to Grant Degrees in Divinity, Law, and Medicine?" It may be obtained from Wyllie and Son, publishers, Aberdeen.—*Lancet*.

## CORRESPONDENCE.

## WORKING OF THE DISPENSARY ACT.

"Bad as the remuneration of our Dispensary Surgeons is, what might it not have been had they remained passive during the legislative campaigns which led to the present arrangements."—MEDICAL PRESS, Aug. 25.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—I am very sorry to say you have fallen into a grave error when you wrote the above paragraph, for it is impossible that an act more degrading or more destructive to the country dispensary surgeon could have been devised; no, not even if the clause which provides "imprisonment and hard labour" for the "medical officer" had been allowed to stand; and if you had the opportunity of a little conversation with them, you would find that more than half of the country dispensary surgeons are so dissatisfied and disappointed that they intend resigning their dispensaries; in fact, no one will remain that can by any means get away. Some with large families and no other provision will probably endeavour to hold on, and a fraction also that have occupations besides medicine: but for the mass, believe me the Commissioners are taking the most summary steps to "eliminate" them (to use the expressive phrase of a high poor-law authority).

I will endeavour now to give you some insight into the way the act is working. The districts are about double the size they ought to be, often extending from ten to sixteen Irish miles from end to end, and you may assume that nearly the entire population (beneath the class of gentleman) is to be attended gratuitously—for there is no limit in the issue of tickets—farmers of forty, sixty, or perhaps more acres, without difficulty, getting the necessary order for the medical officer. We are told to represent to the managing committee any improper person that may be recommended, and that they will cancel the ticket, but you will find this is "a delusion and mockery." The committee seldom meet; at all events, you will be very lucky if they meet before the wealthy farmer has had the benefit of your services for three or four weeks, sufficient time to have cured any ordinary disease; besides all this, it would be very imprudent to make a complaint to the committee. You would almost to a certainty make an enemy of the gentleman who gave the ticket.

And suppose you even brave this, and get the ticket cancelled, you will have gained nothing—the man is cured or the woman delivered; and the next time any of the family are sick, a ticket will be procured from the same committee man, who has only to say the farmer is not then as well off as when his name was cancelled. Heretofore the vaccination contract was worth £10 or £15 in the year, and perhaps half a dozen pounds more were made by vaccinating the children of farmers, shopkeepers, &c. Now you are required to vaccinate all comers.

The arrangements relative to red tickets are very vexa-

tious. Heretofore, I believe, the general rule was, that all tickets should be taken to the dispensary at the proper hour—unless in case of emergency. Now you are required to receive at your residence, at all hours, visiting tickets; in fact you have not a moment to yourself—you have a life of the greatest drudgery. In addition to all this we are bewildered with a tedious and complicated system of bookkeeping. The salary, or the remuneration the Commissioners are pleased facetiously to term it, is £60 a year—less three months pay—for which you are very coolly told the act has made no provision.

I need not tell you that the entire labour of one horse is scarcely sufficient. Probably you will say the private practice indemnifies. But the private practice in the south and west of Ireland in a rural dispensary district is very limited indeed, and even that limited practice has been further limited by the grinding regulations I have before alluded to.

I commend this letter to the consideration of the Council of the College of Surgeons, who, I am sure, had no idea we would be thus treated, when they remarked in their Report of the 20th of May, that "they confidently hoped this act would be beneficial to the medical profession and the public."

For the present I will conclude, I purpose, with your kind permission, returning to the subject, particularly as you so much bemoan the apathy that appears to prevail among us.

Yours truly,

A FELLOW OF THE COLLEGE.

We shall be glad to hear again from our correspondent on this subject, for to say the truth, we do not find many inclined to state their grievances in the same way.

TO THE EDITOR OF THE MEDICAL PRESS.

MY DEAR SIR,—I said in my letter of August 4th, that I would not again trespass on your columns except to ask insertion for a letter of Mrs. M.'s in confirmation of my account of that misunderstanding. You have since, however, published another letter from Dr. Little, and also a document signed by Mr. St. Leger and Mr. Griffith; you will therefore see the justice of inserting the statement of the other arbitrators—a statement in which Mr. Jones, who was called in as umpire, fully concurred.

## STATEMENT.

"Our attention having been called to a letter of Dr. Little's in the MEDICAL PRESS of the 6th of July, 1852, and also to one from Mr. St. Leger and Mr. Griffith in a subsequent number, we beg to repeat our conviction that Dr. Little, by having, in his letter of the 7th of July, alluded to the arbitration, had taken a wrong view of it, it being the expressed wish of the arbitrators that the matter was not again to be alluded to; and the letter of apology (No. 6) was only to be considered an acknowledgment of an unintentional error, Mrs. Davys in her letter having taken on herself the responsibility of the statement made by Dr. Lynn to Dr. McMunn. We have already stated that Dr. Lynn did not get a copy of letter marked No. 6.

Signed,

FRANCIS GILBERT.  
THOMAS YEATES."

You have now, Mr. Editor, seen documents bearing out every statement made by me during this painful correspondence. First, you have the statement made by Captain Gilbert and Mr. Yeates, July 27th, and also their statement of August 17th, to the effect, "that a copy of the letter of apology (No. 6) was not handed to me after the arbitration; that it was only to be considered as an acknowledgment of an unintentional error into which Mr. D.'s communication had led me; and that it was the intention and expressed wish of the arbitrators that the subject of the arbitration was not again to be alluded to." Second, Mrs. D.'s letter, in which she takes on herself the responsibility of the statement I made to Dr. McMunn, and which has been so skilfully used to divert attention from the real origin of the correspondence—namely, Dr. Little's uncalled for attack on the case reported by me in the MEDICAL PRESS. Third, Dr. Whittaker's letter disavowing

the words quoted by Dr. Little as the pretext for his criticisms on the case. Fourth, Dr. Tucker's letter bearing testimony to the truthfulness of my report of the case. Fifth, the extracts from the letter to Mr. F.,—extracts which justify any subsequent want of courtesy on my part. Dr. Little says the letter containing them was written three years ago; if so, it only proves that Dr. Little commenced the system of "stabbing in the dark" (his own words) when I thought we were on friendly terms. I only saw it after the misunderstanding about Mr. M., and could then scarcely believe my senses. Sixth, Mrs. M.'s letter bearing out every particular of the account which I gave of that misunderstanding. Unless unscrupulous assertions and abusive language are allowed to outweigh such evidence as the above documents afford, I do not think Dr. Little will have raised himself in the estimation of the profession by his attack on me.—I am, dear sir, yours very truly,

ROBERT LYNN.

Sligo, September 3, 1852.

#### A BOARD OF GUARDIANS BROUGHT TO THEIR SENSES.

ON the 29th of December, 1851, an order, signed by the relieving officer, was left at my residence, requesting my attendance on Mary White, a pauper, of Evercreech, nearly four miles distant, who was stated to be in labour. As a previous professional engagement prevented my attending, I requested my qualified assistant to go without delay. He went, and arrived at the patient's house before the messenger had returned home. His presence was little required, as the labour had scarcely commenced, the mouth of the womb not being larger than a sixpence. It was the extremely weak and half-starved appearance of the pauper that induced him to remain in attendance. At two p.m. flooding first took place, and upon a further examination it was ascertained that there was an after-birth presentation. The pains having ceased, my assistant immediately gave the ergot of rye, plugged the vagina to restrain the hæmorrhage, and sent a man on horseback to me, requesting a consultation. The messenger came through Bruton to me, at Castle, the distance of seven miles, where I had gone to assist a neighbouring practitioner in the amputation of an arm. As the operation was urgently required, I was unable to leave, but directed that a carriage should be hired as quickly as possible, and that my able and experienced friend, Mr. Stockwell, should be requested to go to Mary White. Mr. Stockwell arrived at Evercreech between four and five o'clock. He found the patient in a very low condition, but the hæmorrhage had ceased. He remained nearly three quarters of an hour in consultation with my assistant. The flooding did not return during his visit. It was agreed that the patient should be constantly supplied with stimulants and nourishment, and if the flooding should return, my assistant was to turn the child and deliver the woman. I proceeded to Evercreech between five and six o'clock, and met Mr. Stockwell on the road. We consulted on the case, which he considered a most dangerous one, and that the patient, when he saw her, was too weak to undergo the operation of turning, but if the flooding returned, he advised me to deliver the woman as a last resource. When I arrived the hæmorrhage had just begun to return, and it was clear that if the operation of turning was not performed, the woman would die undelivered. As there had been no labour pains since the flooding had commenced, the mouth of the womb was not so large as half a crown, and it required no little trouble and difficulty gradually to dilate the opening and introduce my hand. After kneeling from twenty minutes to half an hour on the stone floor of a dirty cottage, the child and after-birth were brought away in the usual manner. The woman did not survive the operation more than three quarters of an hour. It is right to state here, that the patient, before her confinement, was so weak in body and depressed in spirits, from consumption and other causes of a mental nature, that in all probability she would scarcely have survived natural labour. Her doom was sealed as soon as the flooding commenced, and no skill could have saved her life. The following week my account was forwarded, as usual, to the board of guardians, containing a charge of £2 for the case, including the nine hours' attendance of my qualified assistant, Mr. Stock-

well's journey and consultation, and the performance of a difficult obstetric operation by myself. This enlightened board of guardians refused to allow the above fee, and with their accustomed generosity offered me the sum of ten shillings! I appealed to the poor-law board, who, after communicating with the Shepton Mallet Board of Guardians, received from the latter the following truthful and intelligent letter:—

"Shepton Mallet, February 11, 1852.

MY LORDS AND GENTLEMEN,—I am directed to acknowledge the receipt of your letter, No. 3006, dated the 27th ult., containing a copy of a letter addressed to you by Mr. Crouch, medical officer, with reference to a disallowance *in (sic)* his charge for attending Mary White in her confinement. I am instructed to state, that the board of guardians, on receipt of the letter referred to, gave directions to their relieving officer, Mr. Bown, to make inquiries relative to the case, and report thereon. The following facts were stated by him to the board at their meeting of the 10th instant:—"Mr. Crouch was from home when the order for attendance on the woman (which was obtained at nine o'clock in the morning) was left at his residence; that his assistant attended the case, but that he could do nothing to relieve the patient; she was therefore obliged to remain without medical assistance until Mr. Crouch returned home, which was not till seven o'clock in the evening, when the operation described in Mr. Crouch's letter took place, but without any beneficial result, the poor woman having died shortly after. I am to state, that the guardians are of opinion, that had had the patient had the assistance of Mr. Crouch at an earlier period, her life might have been spared. I am instructed to add, that, as a general rule, the guardians consider ten shillings sufficient for midwifery fees, and they are of opinion that in this case Mr. Crouch is not entitled to a higher fee.

Signed for G. M. MACKAY,

J. THOMAS."

In reply to the above libellous production, I informed the poor-law board that not only were its contents manifestly untrue, but that they were contrary to what was stated to the guardians by their own relieving officer, Mr. Bown. The board of guardians still refused to pay more than ten shillings, although the poor-law board twice recommended them to reconsider their decision, and although the meaning of the order is so clear, that "he who runs may read." The order is as follows:—"Provided that in any special case in which great difficulty may have occurred in the delivery, any district medical officer shall receive the sum of £2." The poor-law board having intimated "that it was open to me to take proceedings in the county court against the guardians of the Shepton Mallet Union, for the recovery of a fee for my attendance on Mary White," on the 31st of July last, the chairman, vice-chairman, and clerk of the union were summoned to the county court at Wells. After Mr. Stockwell and myself had given evidence that the case of Mary White was a rare and difficult one, an abortive attempt was made by the defendants to prove that there was a want of skill on the part of my assistant, great neglect on my side, and also that it was not a difficult case. Their witnesses consisted of a medical man, who knew nothing of the nature of the case before he entered the court, and of an old woman, who was not even a village midwife, and had never confined a person in her life. Both of these gave evidence distinctly in my favour. The judge of the court, who exhibited on the occasion his usual acumen, concluded the case by saying—"There is no defence whatever to this action. The plaintiff must have his £2; and it would have been more creditable to the board of guardians if they had consulted Mr. Stockwell about the nature of the case, instead of sending for an ignorant old woman, who scarcely knew her right hand from her left, and whose only clear idea is, that she has had a large family without much difficulty or trouble."—*Mr. Crouch of Bruton, Somerset, in Prov. Jour.*

SUMBUL IN DELIRIUM TREMENS.—St. Petersburg hospital reports say that the root of sumbul proves a rapid and desirable means of cure of the delirium tremens of drunkards, being in very many cases to be preferred to opium. It is especially in the erethritic form of the disease that it is useful, the excitement being quickly calmed, and sleep with general diaphoresis ensuing. It is administered as an infusion (half an oz. to six oz. aq.), a spoonful being given at first every hour, and then every second hour, continuing it for some days after sleep has been procured.

## URATE OF AMMONIA AS AN EXTERNAL APPLICATION IN SYNOVIAL INFLAMMATION OF THE JOINTS.

By W. HORNER, M.D., Pennsylvania.

THE author's acquaintance with the counter-irritant properties of urate of ammonia was accidental. He had a patient who, dissatisfied with his applications, used one of her own to an inflamed joint, which consisted of a mixture of human urine and potter's clay, applied as a poultice. This nasty application having relieved the pain in a few hours, the author was tempted to experiment with it in other cases, substituting a guano poultice for the original. . . .

Having a similar case shortly afterwards in the St. Joseph's Hospital, I tried it in a solution of muriate of ammonia formed into a poultice. No very distinct or satisfactory result followed, and it was discontinued. Having the idea still in my mind, and wishing to be satisfied about it, but reluctant to employ the article resorted to by the poor woman, I determined to find my urate of ammonia in some other form of an easy kind, and for that reason adopted the guano, which has so large a proportion of phosphate of lime, urea, and urate of ammonia in it. A female patient, aged 34, Mrs. C., from Tamaqua, who had for more than a year laboured under inflammation of the right knee, was put under my charge at the St. Joseph's Hospital, October 8, 1851. She had been well attended to by Dr. Scherner, who had conducted her through the most acute period of her complaint. The joint had suppurated, and she came to town with a small fistulous orifice on the inner side of the knee, through which a probe could be easily passed between the tibia and os femoris. From this there came daily a spoonful or more of matter when a plug was withdrawn from the orifice. She still suffered great pain at night, the part was tender, and was in continual uneasiness, and she had some slight fever in the afternoon. Here was exactly the case to try the efficacy of urate of ammonia, as naturally formed in animals. I accordingly obtained some guano, and had it made into a hot poultice with clay. The joint was kept enveloped in the poultice, with frequent changes, for nearly the remainder of the month, at the end of which time a very marked improvement had taken place in the amount of pain, and also in the degree of swelling, and the purulent discharge had almost ceased.

The application produced a very copious vesication of the knee, and it had to be weakened to reduce the caustic qualities. Having conducted this treatment as far as seemed necessary, the skin was permitted to heal. Some little pain recurring afterwards, she was blistered for it; that getting well, the emplastrum calefaciens was applied, and the leg was also kept supported by an extending band on the ankle, and a counter-extending one on the thigh, their action being sustained by a splint on the outside of the limb. At the end of six weeks (Nov. 25th) she has left the hospital without pain or uneasiness in the knee. The joint is in a state of false ankylosis, and straight. I have covered the knee with emplastrum adhesivum, and secured it in that position with strong pasteboard splints, moulded to the knee, and have recommended her to keep it so for two or three months, until all danger of secondary suppuration be removed. Probably at the end of this time the judicious use of frictions and of Stromeyer's screw-splint may impart some flexion to the limb.

The hospital record sheet shows the following details of dates, which may be inserted in this place:—October 9th: Poultice of guano (urate of ammonia) and potter's clay, equal parts. 10th: Poultice has blistered; it was discontinued, and simple cerate applied. 11th: Patient has less pain; soreness of knee reduced, and not so much swelling; a poultice with one-third of the urate of ammonia and two-thirds potter's clay. 13th: Vesication. 14th: Quantity of urate reduced to one-fourth of poultice; treatment continued pretty much in this state to near the end of the month; vesication by emplast. cantharid. about this time. 28th: She was permitted to eat as she pleased. November 5th: Emplastrum calefaciens. 12th: Discontinue

emplastrum calefaciens, and reapply the urate of ammonia, on the 14th of October.

While this case was in progress, another occurred in a boy who had the knee-joint opened by a cut of half an inch or so in length. Synovial inflammation followed, with the ordinary symptoms. Its usual acute period was passed through, under the depletory antiphlogistic treatment, and with evaporating lotions to the part. The disposition to fall into the chronic state, attended with tumefaction, was relieved by five days' use of the same agillacious, uro-ammoniacal poultice. The ward-sheet exhibits the following entries, in regard to this case:—Patient, Timothy Roach, aged 19, admitted September 23rd, a day or two after the accident; knee painful and stiff, somewhat swollen; rest and fomentations of warm water directed on that day; also loss of ten ounces of blood from arm. 24th: Local bleeding by scarified cupping; fomentations continued. October 4th: Warm fomentations to this date; in the meantime an evident articular effusion has occurred in the synovial membrane of the knee; a blister-plaster, four inches by four, was then applied. 6th: Blister-plaster two inches by three. 7th: The patient so much relieved from pain as to be permitted to leave his bed, and promenade with a crutch. 9th: Some aching and tumefaction indicated a persistence of articular irritation; the poultice of urate of ammonia (guano) one-fourth, potter's clay three fourths, was then applied hot, with frequent renewals to the 14th of October, at which time all the symptoms were relieved. The patient was discharged cured on the 15th.

The above cases are reported much in outline. I shall continue, as opportunity offers, to test the value of the above remedy, and also compare its results with other remedies. It appears to me to have some special qualities, which are of a highly beneficial kind in the affections alluded to. It is so active a revulsive when applied strong, that I have no doubt of there being many cases of serous inflammation in which it may be usefully resorted to. I would here suggest a trial in puerperal peritonitis and in pleurisy. I see no objection except the odour. The poultice of guano and clay dries very quickly, so that it is better to shield it with oiled silk or India-rubber cloth. The clay I look upon as simply a vehicle, but it may also have some physiological action from its physical properties in regard to moisture. The analysis of the best guano by the chemist, presents the following constituents, which are mentioned here for facility of reference. The proportions will vary according to their atmospheric exposure and to the degree of adulteration in trade:—Uric acid, thirty per cent.; uric acid with ammonia; carbonate of ammonia; muriate, oxalate, and phosphate of ammonia; free ammonia; phosphate of soda; phosphate of lime; sulphate of potash and soda, and oxalate of lime. It is the large quantity of ammonia in it which makes it so active a stimulant to vegetable growth, and so disagreeable to the smell.—*Phil. Med. Examiner.*

BRONCHOCELE IN A NEW-BORN INFANT.—I was this morning present at a labour of a rather tedious description, and on the birth of the child, a full-grown female infant, we were astonished to find it was the subject of a very large bronchocele, nearly the size of a large apple. The complaint is very common in the vicinity, but the mother herself has never suffered from it beyond a very slight degree. She has had nine children, and her prior confinements have been quick and easy. The bronchocele evidently interfered with the flexion of the head on the breast of the child; and we know that this flexion is necessary to bring the occipito-bregmatic diameter into coincidence with the right oblique diameter of the pelvic inlet. The child was dead, evidently asphyxiated. The case proves (if additional proof be necessary) that the disease of bronchocele is a blood disease, and not dependent on modes of life, &c. In some writers it is stated not to exist before puberty, but this is quite incorrect. I know one case occurring in an infant ten weeks old, and another in a little girl aged nine years. It is singular that the slight amount of bronchocele from which the mother suffers has only appeared during this pregnancy.—*Mr. Smith of Chesterfield in Lancet.*

# EXAMINATION OF OINTMENTS CONTAINING MERCURY.

By M. BOBIERRE.

HAVING had occasion to examine some citrine ointments employed by a woman who was accused of illegally practising medicine, I experienced some difficulty in ascertaining the chemical characters of the metallic substance present, in consequence of the small proportion of it contained in the ointment, and also in consequence of the ointment being very old. The following method of operating proved so successful, that I am induced to record it for the benefit of those engaged in such investigations. It serves to isolate mercury in a few minutes from its combination with oxygen and fatty acids. However small the quantity of mercury present may be, the effect is, nevertheless, distinct. The ointment to be examined is melted by the application of a gentle heat, and a small quantity of essence of citron is then added to it. Under the well-known reducing influence of this hydro-carbon, the ointment acquires a gray colour, which effect is to be promoted by agitation. After about five minutes, the ointment being still kept melted, three times its volume of ether is to be added, the whole mixed together, and then allowed to stand. The supernatant liquid is then to be decanted, and the residue washed several times with ether. The mercury left at the bottom of the vessel may now be dissolved in nitric acid, and tested with the usual reagents.—*Jr. de Chim. Méd. and Ph. Jr.*

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

## THE COMPOUNDING DEPARTMENT AT

### G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

## BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Just published, 8vo, pp. 96, price 2s. 6d.,

## A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

## THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

## THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Wednesday, September 8, 1852.

### KING'S COLLEGE HOSPITAL.

*Spasm of the Muscles of the Larynx simulating Hiccup—Tania Solium in the Bowels.*

(Under the care of Dr. TODD.)

THE physician has now and then to treat convulsive affections of a distressing kind, such as tetanus, hydrophobia, catalepsy, eclampsia, &c.; and he has the sad consciousness that, in several of these, his art cannot ward off the fatal issue. Where, however, convulsive diseases are clearly traceable to an irritation producing spasms by reflex action, we feel confident that by removing the irritating agent we have a very fair prospect of conquering the abnormal symptoms. Hiccup is one of the most common and ordinary spasmodic manifestations of this kind, and it is strange that the origin of this act should still be veiled in obscurity. It is, however, very probable that the contractions of the diaphragm called hiccup, or singultus, are of a reflex nature; but the various causes which are likely to give rise to this reflex action have not as yet been clearly enumerated or classified.

Were our knowledge regarding hiccup more precise, there would of course be less risk of confounding it with other spasmodic expirations followed by sudden closure of the glottis, for the sound produced in the former and the latter is very much the same. We had lately a favourable opportunity of ascertaining the truth of this analogy in a patient under the care of Dr. Todd.

By an interesting coincidence it happened that we saw, a short time previously, in Dr. Burrow's ward, at St. Bartholomew's Hospital, a patient similarly affected; but there was this difference between the two cases, that the presumption of the hysterical diathesis was much stronger in the second than in the first.

It is not difficult to understand how uterine derangement should be connected with a spasmodic affection of the larynx, for this influence is made very familiar by the frequent occurrence of the globus hystericus. Nor is it less known that, even with the male sex, there is a distinct

connexion between the organs of generation and the larynx, the voice being infallibly modified by the greater or less development of these organs. It will, however, be seen by the following details, obtained from Mr. Masfen, physician's assistant to the hospital, that the exciting cause of the singultus in Dr. Todd's patient, which was at first thought to be the presence of the tapeworm, is still somewhat wrapped in obscurity.

Mary R—, aged 33, the mother of two children, the youngest of whom is seven years old, was admitted April 14, 1852, into Lonsdale ward. The patient had always enjoyed good health until the present attack; but about six weeks before her admission she was suddenly seized, without any apparent cause, with what she describes as hiccup, and this state continued the whole of the time until she was received into the hospital.

The woman stated that, besides the hiccup, she had been troubled much with tapeworm, the presence of which did not, however, give her much uneasiness. Occasionally small portions of the parasite passed in the stools; the catamenia were regular, but the patient appeared thin and ill-nourished.

The so-called hiccup continued after the woman's admission, and prevented her from sleeping. On a careful examination, it became, however, evident that the convulsive affection was not genuine hiccup, inasmuch as there was no perverted action of the diaphragm. The affection consisted of very frequent and short acts of expiration, accompanied with a crowing sound; this sobbing or singultus appearing to arise from spasm of the muscles of the larynx, of the sterno-mastoid, the muscles connecting the larynx with the sternum, the mylo-hyoid, and scaleni muscles. Dr. Todd, suspecting that these convulsive actions might depend on some irritation caused by the tapeworm, directed, after the usual preliminary treatment, that the oil of male fern should be administered. This medicine brought away a considerable portion of the body of the worm, but not the head; and this evacuation did not produce the slightest visible effect on the laryngeal spasms.

The patient was then ordered nourishing diet and tonics,

with opiates at bedtime, and a cold shower-bath every morning. The opiates procured rest at night; during sleep the respiration was normal, and the singultus absent. A few days after admission the symptoms were so aggravated, that Mr. Bridgewater, then physician's assistant, made the patient inhale chloroform. He removed the apparatus when the anæsthetic agent was just about producing its effects, and noticed that during the inhalation the spasm subsided gradually and soon disappeared altogether, the breathing becoming quite calm. But in less than five minutes the affection came on again. Under these circumstances Mr. Bridgewater resumed the use of the chloroform, but this time he put her under its full anæsthetic power. The breathing remained perfectly calm for about twenty minutes after the patient had ceased inhaling; but the spasm returned gradually as she recovered from the effects of the chloroform.

She continued much the same for six or eight weeks after her admission, having intervals of more or less freedom from the affection, the contractions being, however, now and then aggravated, and being attended with increased crowing sound.

On June 8th, about two months after admission, a blister was applied, covering the whole of the front of the neck from the chin to the sternum, and the vesication was kept open by savine ointment. Intense pain was now produced on every contraction of the laryngeal and neighbouring muscles; in a short time the singultus gradually subsided, and finally disappeared completely. The blister was kept open for nearly three weeks, at the end of which time it was allowed to heal. The spasmodic affection soon returned, however, and was quite as inveterate as ever. The pseudo-hiccup was very loud, it could be heard through the whole ward, and resembled in some degree the peculiar sound sometimes produced by turkeys.

A second blister was applied to the same spot on the 1st of July, about three weeks after the first, and with the same effect as before. The spasm and crowing sound entirely ceased, and did not recur till about a fortnight afterwards, when the blister had been allowed to heal. Change of air being thought advisable, she was made an out-patient for a few weeks, with the understanding that she was then to return to the hospital.

Has the presence of the tapeworm anything to do with the pseudo-hiccup? Perhaps so; the head was not expelled, and it is difficult to say whether there is more or less of the body left behind. The probability, however, is, that the laryngeal affection is independent of the tænia. As to the effect of the blister on the neck, it presents a very curious fact, for it would at first sight tend to prove that the affection was feigned. But on a closer inspection it will be found that the nervous energy of the surface being changed by the intense inflammation resulting from the cantharides, the reflex action could no longer be produced, since no primary impression, or a faint one, could be made on the nervous ramifications of the tegumentary surface. Still it remains a very instructive fact, that the spasmodic contractions ceased as soon as they could not continue without pain. We understood that this method of treatment had been resorted to by Dr. Murphy of University College Hospital, with permanent success.

We alluded above to a case of this kind under the care of Dr. Burrows, at St. Bartholomew's Hospital. Here the girl was decidedly hysterical; the symptoms were just as well marked as in Dr. Todd's patient, but they soon gave way to the treatment in general use against hysteria. We often listened with peculiar interest to the clicking or crowing sound produced both by Dr. Burrows' and Dr. Todd's patients, and took great care to question them both very closely. The first evinced decided signs of hysterical eccentricities, whilst the second did not exhibit a trace of this peculiar diathesis. As to any deception which might have been practised by either, we would unhesitatingly state our belief, that, as far as we can see at present, the effort necessary for keeping it up seems physically impossible.—*Lancet*.

## CASE OF HYDROPHOBIA.

By J. A. LAWRIE, M.D.,

Professor of Surgery in the University of Glasgow.

(Read before the Glasgow Medico-Chirurgical Society, July 1852.)

ON Wednesday, 9th of June, I got a note from my friend, Mr. Hislop of Renfrew, requesting my immediate attendance, as he feared he had met with a case of hydrophobia. I instantly obeyed the summons; but before detailing the symptoms which I observed, I would call your attention to the following statement, with which Mr. Hislop has most kindly furnished me, and which I give nearly in his own words:—On Tuesday, 8th of June, Mr. Hislop was hurriedly called, about midday, to see Miss M., a robust healthy-looking girl, of twenty. He was informed that on Monday, 7th of June, she had consulted Dr. Robertson for symptoms which appeared to him to be hysterical. Dr. R. prescribed a saline laxative, which did not relieve her. Next morning, the character of the symptoms appearing unchanged, the aromatic spirit of ammonia was ordered in repeated doses. The girl complained to Dr. R. of depression of spirits and general uneasiness, but especially of globus and a feeling of suffocation. The only peculiarity, hardly noticed at the time, was that she said—"I cannot swallow the medicines." In fact, difficulty of swallowing did immediately occur during her attempts to take each dose of the aromatic spirit, and with accompanying spasms in the throat, had so much increased, that when she was offered her midday dose, she threw the glass from her, rushed down stairs, and casting herself into her aunt's arms, exclaimed she was dying. It was then that, in consequence of Dr. Robertson's absence, Mr. Hislop was hurriedly summoned, and saw her for the first time. He found her in considerable distress, imploring relief from a ball of wind in her throat, which she every moment expected would suffocate her. She made frequent efforts "to break the ball," and occasionally succeeded after much retching, in getting rid of a little flatus. Along with this she had distinct spasmodic paroxysms, occurring perhaps every five minutes, during which she clutched her throat with both her hands. She seemed much excited. Pulse 120; bowels very constipated, no stool for eight days; catamenia quite regular. The opinion Mr. H. formed coincided with that given by Dr. Robertson, that the case was one of acute hysteria. He immediately put gr. i. ss. of tartar emetic into a teaspoonful of water, and with considerable difficulty persuaded the young woman to swallow it, which she did with a peculiar snap and some effort. In ten minutes he repeated the dose, and remained with her three-quarters of an hour. She did not vomit, but her pulse fell, and the spasms were quieted. He ordered a purgative enema, and left her. During this lengthened visit a circumstance occurred which is worth mentioning. The girl was engaged to be married; her intended called, and remained with her about twenty minutes. Immediately before he entered the room, she was complaining very much of the spasms in her throat; but no sooner was she aware of his presence than she seemed to forget her ailments, and talked, laughed, and jested, as if she were quite well. No sooner, however, did he leave her than her symptoms returned. Mr. H. called at eight in the evening, and found her much better; the enema had acted freely, and during its operation she had vomited a quantity of bilious matter. She was in good spirits, and attributed her illness to constipation and "cold." June 9th: At one o'clock in the morning, Mr. H. was roused by a loud and urgent summons to visit his patient. He found that, although she had been comparatively quiet in the early part of the night, she had not slept. The spasms had returned, and been much aggravated by an attempt to drink some ginger beer. They were now almost without intermission, and so violent that when they came on she would spring suddenly out of bed, and cling to those beside her in an agony of despair. Her pulse was 150, and very full. She was still making constant efforts "to break the ball in her throat," and complaining of pain, which he attributed to these efforts, in the

regions of her heart and stomach. He resolved to bleed her, and with some difficulty, on account of her constant change of posture and unsteadiness, took fully xxxiv. of blood. The spasms subsided to a slight occasional sigh, and she seemed much relieved. She soon complained of thirst; the offer of water seemed to produce a spasm, which was renewed by her attempting to swallow it, but she appeared to get over a mouthful with some difficulty. She next said she was hot. Mr. H. lifted his hat, and began to fan her face gently; but each impression of the air on her face brought back the spasm. The suspicion of hydrophobia now for the first time crossed his mind. At this juncture he had some conversation in another room with his patient's aunt, with whom she resided. No other person being present, he took the opportunity of asking if her niece had ever been bitten by a dog. She seemed surprised at the question, and after enjoining him to secrecy, said that her favourite dog, Neptune, "had set upon her, the day before he died, and scratched her back." (The history of the dog, and of this attack, will be given in the sequel.) On returning to his patient he found her much easier, and left her at four o'clock, with directions that she should have a purgative enema at six o'clock, if awake.

At half-past eight a.m., Mr. H. was again hurriedly summoned. The enema had come off, and brought with it *only a little blood*—since which the paroxysms had gone on increasing in frequency and violence, and the mere idea of swallowing seemed to induce them. She had occasional vomiting of bilious matter. Turpentine was applied to the back and chest, mustard to the feet, and a blister to the back of the neck—all without benefit; indeed the vapour of the turpentine proved a source of great annoyance. By eleven a.m., the vomiting had become almost constant, and soon assumed the appearance of "coffee grounds."

I saw her about a quarter to one p.m., and was much struck with what I witnessed. On entering the bedroom, I saw a robust, fine-looking young woman in bed, seemingly under great suffering. She turned her head towards me as I entered, with a sudden movement, and I shall not soon forget her wild expression as she gazed at me for an instant, and threw herself back on her pillow. I especially remarked the following particulars:—

(a) The flash of her eyes—wild, excited, half-hopeful, half-defiant—such as I had never remarked in a sane patient before.

(b) Her great suffering. Her constant cry was,—“Oh! what I'm suffering! Oh! what suffering! What have I done that I should suffer thus?”

(c) Her restlessness and strength. She was never for one moment at rest. She moved with ease, and any attempts to restrain her movements were difficult, and required considerable effort on the part of the attendants.

(d) Salivation. A frothy saliva was constantly collecting in her mouth and between her lips. With her left hand she wiped this saliva from her lips, and rubbed it on the edge of the bedding. I particularly remarked that, when her left hand was unoccupied, she did not spit, but cleared away the saliva with her thumb and forefinger, rubbing it on the bedding, or spattering it about, regardless of where it fell. When her left hand was held, and she was not vomiting, she was unceasingly spitting, and such was the quantity discharged, that before I was many minutes beside her my hands and dress were spattered over with the white froth, which issued in profusion from her mouth.

(e) Vomiting. This was, perhaps, her most distressing symptom. It was almost constant, difficult, painful, and straining. The quantity of matter discharged was not great, but was slimy, and of a "coffee grounds" appearance.

(f) Thirst—*desire for liquids—and power of swallowing.* She complained of urgent thirst, with burning in her mouth, throat, and stomach. She did not appear to have any dread of liquids, nor did she exhibit any horror when it was proposed that she should drink to quench her burning thirst; on the contrary, she freely discussed what would be best for her, asked if she might have ginger beer, and

showed no annoyance when her aunt tried to jest with her on the love she had shown for so vulgar a beverage as gin and water. When liquid was actually brought to her, the following circumstances were well marked. She would not allow any one to put it into her mouth, but sat up in bed, and most reluctantly, and at last with a quick movement, seized the glass. She held it for an instant with a convulsive grasp, her hand quivering and spilling a portion of its contents, and then threw (pitched) the remainder into her mouth. Having emptied it, she cast the glass from her, regardless where it fell, and convulsively clutched her throat with her hand. A rapid, violent, convulsive movement of the throat and neck followed, and the fluid was jerked out by a motion not unlike that by which it was pitched in. The attempt to swallow increased the irritation of the stomach, and she immediately threw herself across the edge of the bed, and renewed her painful straining vomiting. It was very doubtful if she *swallowed* any liquid, a convulsive closure of the pharynx seemed to arrest it and eject it with an irresistible and powerful effort. Her existence at this time may be described as consisting of an unceasing round of tossing, complaining, salivating, vomiting, with convulsive movements in her throat, and a sense of suffocation from a never-absent indestructible ball, to relieve which she clutched her throat with her hands, as if she would tear out what she could not otherwise rid herself of.

(g) Her pulse was at least 150, regular, but not strong.

(h) The intellectual faculties seemed unimpaired. She moved her tongue and jaw with perfect facility, and articulated quite distinctly and with great volubility. There was no appearance of mania or furor—not the slightest disposition to hurt herself or any one near her; on the contrary, her manner to her attendants was kind. There was no peculiar sound of her voice, nothing which could at all be likened to the barking of a dog.

(i) She did not appear in the slightest degree to connect her illness with the bite of her favourite dog, or to have the least suspicion of the nature of her disease. She was early impressed with the idea that she was to die, and told her aunt that her "doctors did not know what was the matter with her, and she wished that her body might be opened after her death." This was said on Tuesday forenoon, before her medical attendants were at all alarmed as to the issue of her illness. She showed no fear of dogs. On the forenoon of the day on which she died, a terrier having come into her bed-room, her aunt ordered it to be put out. She seemed sorry when it left her, and, looking after it, said, "Poor Jack!"

Such, so far as I can recollect, are the principal circumstances which I remarked in this poor girl.

The vomiting of coffee ground matter, with burning in her throat and extreme suffering, being very prominent symptoms, I confess that the suspicion immediately crossed my mind that the case was one of poisoning. I therefore gave directions that the matter ejected should be carefully preserved. I took a part of it with me to Glasgow, and gave it to Dr. R. D. Thompson, who, with great inconvenience to himself, but with that desire to oblige, and to make his high chemical attainments of use to his less qualified brethren, for which he is so much distinguished, immediately ascertained that it contained no acid inorganic matter. I thought it necessary to communicate my suspicions to the girl's aunt, as well as to her medical attendants, and some circumstances being mentioned which rather seemed to corroborate my views and to implicate our patient, I, with their sanction, indeed at their express desire, stated them to the poor girl herself. She gave them a distinct, emphatic, and circumstantial denial, but showed no anger or irritation that I should entertain them. Her answers and her manner satisfied me on two points already adverted to—that her intellect was quite entire, and that there was a total absence of furor or mania. In a word, that the peculiar symptoms which I witnessed arose from overwhelming bodily suffering, and not from mental aberration.

I remained with her for fully two hours, during which

she had two large opiate enemata, and hydrocyanic acid by the mouth. As I have already said, she did not refuse to attempt to swallow, but I doubt very much if any liquid reached her stomach. The medicine was pitched into her mouth, and the glass thrown from her hand, in the manner I have already described.

I had chloroform with me, and after the first opiate enema I proceeded to try it in the usual way. Great difficulty was experienced in getting her to inhale it. Not one instant was she at rest. Her hands being held, and her head steadied, I held the napkin before her face; but her gurgling breathing and livid countenance soon warned me that I must desist. Had I persisted, I am satisfied she would speedily have been suffocated.

I sat beside her watching the symptoms for an hour; and seeing that two drachms of laudanum by enema had no effect, and that the exhibition of medicine by the mouth was hopeless, I determined to try the chloroform again. Having laid her upon her back, with her head raised and steadied, and her hands forcibly held, I kept the napkin well saturated with chloroform opposite to, but two or three inches from, her face. She was soon gently under its influence, but never to complete insensibility. The effect on the symptoms was that the vomiting completely ceased, and the restless jactitation disappeared, or was easily controlled; but she did not cease hardly for one instant to speak in the most energetic voluble strain, and the froth continued to issue in considerable quantities from her lips. Her pulse varied, but frequently fell to a little above, sometimes even below, 100. I continued to hold the napkin and watch the effect of the chloroform for about an hour, and having satisfied myself that, whatever the ultimate result might be, the inhalation was alleviating her sufferings, I left her, suggesting to Dr. R. and Mr. H. the propriety of continuing the chloroform as long as they thought they could do so with safety. I returned in the evening, and found that shortly before my arrival she had been relieved by death from her terrible sufferings. Mr. Hislop informed me that the chloroform had been continued with great relief till about half-past four o'clock, when the vomiting and spasms returned, and the pulse became so feeble that it was deemed prudent to omit it. The difficulty of swallowing continued to the last. "About twenty minutes before her death," says Mr. Hislop, "she complained of thirst, and I offered her a glass of gin and water. On taking it in her hand she became violently agitated, and in attempting to carry it to her mouth spilt it on herself and her attendants. She said it was the gin which prevented her swallowing, and I gave her pure water. The result was the same, and I do not think she swallowed a drop of the fluid. She sank rapidly from five o'clock, and died rather suddenly at seven in a violent spasm, which seemed to suffocate her in an instant."

Her aunt gave her willing consent that the body should be carefully examined; and on Thursday evening, about twenty-four hours after death, Dr. Aitken and Mr. Macdowal gave me their valuable assistance in effecting a careful and minute examination. The following is Dr. Aitken's report:—

*"Morbid Appearances in a Case of Hydrophobia."*

June 11, 1852.—Along with Dr. Lawrie, I examined this evening, at Renfrew, the body of a female, who had been dead about twenty-four hours, and who had every appearance of having been a well-formed healthy person, about 19 years of age. The weather was moderately warm, and the body appeared to be more than usually livid, especially towards its posterior aspect; the eyeballs were somewhat sunk within the orbits, and no post-mortem rigidity existed in the limbs. The bites of the dog appeared as the cicatrices resulting from the indentation of three teeth; but they were so completely healed up and obscured by the general lividity of the parts, that their position required to be pointed out to us before we could observe them. When thus pointed out, however, the cicatrices were perfectly distinct, consisting of a glistening pellicle of skin, and not differing from the cicatrices of any incised wound. On

dissecting the cicatrix cuticle, it was found very loosely attached to the areolar tissue below; but no change could be observed in the parts, nor any accumulation of fluid different from what could be pressed out of any other part of the areolar tissue of the body. The bites seemed to have been inflicted on the back, about two inches to the left side of the spines of the dorsal vertebrae, a little below and to the vertebral side of the inferior angle of the scapula.

The contents of the cerebro-spinal cavity were next examined, but no unusual appearance was observed, if we except a slightly increased vascularity of the membranes surrounding the upper part of the spinal cord, chiefly in the dorsal region and vicinity of the brachial plexus of nerves. This vascularity was accompanied in some places with a slight extravasation of blood on the outer surface of the membrane, and this extravasation was more particularly evident about the middle of the cervical region of the cord.

The encephalon having been removed, its nerve substance, more especially in the vicinity of the origin and course of the roots of the eighth pair of nerves, was carefully examined, both microscopically and otherwise, but no structural lesion could be observed in any part; on the contrary, the texture of the brain, spinal cord, and nerve, was firm, and the fluid contained in the cavities, both as regards quantity and quality, appeared to be natural.

Turning to the thoracic and abdominal cavities, we found the lungs generally more vascular and more red than usual, but otherwise healthy. Heart also was healthy; and the blood, where found in quantity, was fluid. The papillae on the back part of the tongue were much enlarged, and the whole of the pharynx, along with the epiglottis and larynx, as far down as the vocal cords, were much congested, and covered with a tenacious frothy mucus, tinged with blood. On removing this tenacious mucus from the cavity of the larynx, its surface was here and there observed to be dotted over with little swellings, about the size of pin heads, projecting from the surface. Examined microscopically, they seemed to consist of accumulations of little cells, varying in size from that of a human blood corpuscle to a pus corpuscle; all of them were more or less granular, and some of them nucleated.

The stomach and intestinal canal were removed with their contents for chemical analysis and careful observation. The contents of the stomach consisted chiefly of a fluid, resembling in appearance coffee grounds; the granular and more solid particles appeared under the microscope to be made up of coagulated blood, more or less changed. Similar contents existed throughout the rest of the tube. The mucous membrane of the stomach presented a very much congested appearance, and more especially large patches near the cardia, where in many places streaks of blood could be seen extravasated on the mucous surface. Similar highly congested patches occurred in many places throughout the small intestine, with similar extravasated streaks of blood. These patches varied in size from three to four or even five inches in extent, and in the midst of them, both in the stomach and intestine, air was so abundantly extravasated as to inflate the submucous areolar tissue, and raise the membrane into the form of little air-vesicles, resembling in appearance the texture of the lungs in emphysema. All other organs were healthy.

(The cicatrices of the bite, as well as the tongue, pharynx, and larynx, are preserved in the Pathological Museum.)

WILLIAM AITKEN, M.D.,

Demonstrator of Anatomy, College, and  
Pathologist to the Royal Infirmary of Glasgow.

Dr. James A. Lawrie, Professor of Surgery."

To complete the narrative of this interesting case, I must turn as briefly as possible to its history previous to the 7th June. Mrs. W., the aunt of the patient, had a large dog of the St. Bernard's breed. By all accounts it was a remarkably fine animal, on which she set so high a value that she had refused £20 for it. It was particularly attached to the unfortunate subject of this case, and seemed to take

pride in being her attendant and protector. About the 1st of March it became suddenly ill, and a gamekeeper in the neighbourhood pronounced it to be affected with severe inflammation, the consequence of poison maliciously administered to it. He bled it, and directed it to be put into the coach-house loose, and to be fed upon warm gruel. Immediately before going to bed on the night of the 1st of March, Mrs. W. placed a basin of gruel before the dog, and set another at the side of the fire to be ready for it in the morning. About 'six o'clock she called her niece, and asked her to see how "Neptune" was, and to take him his gruel. The poor girl got out of bed, threw a light shawl loosely over her shoulders, and did as her aunt had desired. When she was leaving the coach-house the dog endeavoured to rush past her and escape, whereupon she closed the door, shutting herself in with her back towards the dog. He instantly sprang upon her, seized her by the left shoulder blade, sank his tusks into her back, and bit or scratched her on her face. Her aunt, when speaking of this attack, endeavoured to make light of it, but one of the servants assured me that the infuriated dog was "worrying" the poor girl, and that she might have been killed had some one not promptly come to her assistance. When the door was opened the dog made his escape, remained away the greater part of the day, and returned in the afternoon of his own accord. He was again shut up in the coach-house, and became quite furious, tearing the door, and every piece of wood he could get hold of. He was so bad that a veterinary surgeon who was asked to see him, was with difficulty permitted to open the door; and what food and medicine he got subsequently was pushed under it. He died the following morning. No suspicion was entertained of his being rabid. On the contrary, so firmly was Mrs. W. persuaded that he had been poisoned, that she urged the public prosecutor to take up the case, and had the body sent to Dr. Mackinlay in Paisley for examination. This latter step was not taken till the 8th of March, by which time the carcass was putrid; and having been previously cut up by a gamekeeper, admitted of a very imperfect examination. The stomach was examined by Dr. Mackinlay, jun., who kindly informs me that he could discover no poison. Mrs. W. publicly offered a reward of £5 to any one who would assist in discovering the person who administered the supposed poison. No informant appeared.

The above statement can hardly leave a doubt as to this animal having died furiously rabid.

*Remarks.*—The first question which suggests itself in this, and all similar cases, is, "Was this really hydrophobia?" Now, it does appear to me, that if we are to admit the existence of hydrophobia as a specific disease, we cannot refuse our assent to this being an example of it. The history of the dog, the history of the girl, the peculiarity of the symptoms, and their rapidly fatal termination, appear to me to be as clearly traced, and as well marked, as we could possibly desire. The diagnosis of hydrophobia ought not to be difficult. I have heard experienced surgeons assert, that it so much resembles tetanus that they are in reality the same disease. It has been my misfortune to see too many cases of tetanus, and only this one case of hydrophobia; but symptoms more dissimilar than those of traumatic tetanus, and the sufferings endured by this unfortunate girl, I have never witnessed. It much more resembles acute hysteria. The globus and incessant tossing were well marked; but although the desire to move was irresistible, the motions had no appearance of being involuntary, or associated with insensibility. The attempts at swallowing brought out symptoms such as I have never before seen, and which appeared to me quite diagnostic between this and any other form of disease. The constant discharge of froth from the mouth was also a very peculiar symptom. My first impression was, that the girl was poisoned. The same suspicion had been strongly entertained regarding the dog. I have only seen one case of pertinaciously concealed suicide from arsenic. In it the symptoms closely resembled those of cholera, and were mistaken for that disease. There was no difficulty of swallowing: the cramps were most overpowering; the vomiting and purging profuse; and the

"natural characters" of the case very different from those of Miss M. Still I think hydrophobia deserves the careful study of the medical jurists.

*The prophylaxis* in this case was very imperfect. Mrs. W. sucked the wounds on her niece's back with her mouth, carefully washed them and dressed them with simple domestic remedies. Nothing else was done, and they healed readily.

*Period of incubation* was about ninety-eight days, certainly beyond the average.

*Predisposition and Predisposing Causes.*—The girl's temperament was ardent and excitable, with a full share of self-will. In January she was engaged to be married to a youth, who took small-pox and died. She persisted, in spite of all remonstrance, in attending upon him, and there is some reason to believe that she took the disease in a very modified form. In a few months after her first lover's death, she was engaged to be married to a second. Her aunt disapproved of the marriage, and for some time keenly opposed it, but was constrained to give her consent a short time before the symptoms of hydrophobia appeared. Powerful mental emotions very frequently precede the first threatenings of hydrophobia, and this case adds one to the number which make it probable that they may act as predisposing causes. Fear had no share in it. The girl had no suspicion of the nature of her illness, and no dread of dogs.

The stage of *recrudescence*, as it is somewhat barbarously called, was altogether absent in this case. She was not heard to complain of her shoulder or face, and Dr. Aitken's accurate report shows that the cicatrices were perfectly normal.

*Morbid Anatomy and Pathology.*—The appearances discovered by Dr. Aitken's careful examination confirm the opinion, that congestion and extravasation of blood connected with the spinal cord and mucous and sub-mucous tissues, with prominence of the mucous papillæ, constitute the principal morbid appearances hitherto discovered in hydrophobia. It seems highly probable that these are effects, not causes, of the disease, or if causes, are but fragments of the efficient cause. What that cause is, or how it acts, is still a mystery. That it is a morbid poison I have myself no doubt. That it may remain in the system for an indefinite period, and then be thrown off, or be brought into play by secondary causes, seems highly probable. I am not disposed to assign any limit to the period of incubation. The poison of syphilis may lurk in the system undeveloped for years; and why not that of hydrophobia?

*Treatment.*—The nature of the disease not being suspected until the symptoms were fully developed, the treatment was more directed to meet symptoms than to arrest so fatal a malady as hydrophobia. Still it was sufficiently active, and conducted on unobjectionable general principles. I was anxious to give sedatives and chloroform, especially the latter, a fair trial. Great caution is necessary in using anæsthetics in this disease. If carried so far as to prevent expectoration, the copious secretion of frothy saliva is almost certain to suffocate. As exhibited in this case, chloroform gave great relief; but as a curative it was powerless. I have tried it freely in tetanus with the same effect. It diminishes pain, but cannot cure; indeed, I fear its tendency is rather to shorten than prolong life. After my experience in this case, I should consider all attempts to treat hydrophobia by medicines given by the mouth as worse than useless. If we look upon the disease as a morbid poison, acting in an unknown manner on the nervous system, our indications will be to allay the consequent irritation, and fight against death with the hope that the poison may exhaust itself before life is extinguished. In this view strong soup, wine and brandy, given by the rectum, with free doses of sedatives exhibited in the same manner, would constitute the most rational treatment. We must not despair of discovering some medicine (possibly some well known medicine applied in a novel manner, as ether by inhalation), which will prevent death until the disease exhaust itself. Perhaps anæsthetics, early begun

before the stage of acute spasm and exhaustion have set in, may be of use. All treatment, whose effect is to diminish strength, should be discarded.

*Frequency of the Disease.*—Until within the last three years, hydrophobia was certainly a rare disease in Scotland. In 1849 a case occurred at Dalkeith, and no fewer than three perfectly authenticated cases are recorded in the *Monthly Journal* as having occurred in the east of Scotland in 1850. When lecturing on this disease during last session, and adverting to these cases, I stated that, so far as I knew, no unequivocal case had been seen in Glasgow or its neighbourhood for at least a quarter of a century, but that, in all probability, twelve months would not pass and leave us in the same boasted immunity. It is remarkable, that about the very time that I made that statement the seeds of the disease were being implanted in our unfortunate patient; and it is not much less so, that I should have been called upon to assist in its treatment—*Monthly Journal of Med. Science.*

#### ON THE EMPLOYMENT OF THE CHLORIDE OF SODIUM IN THE TREATMENT OF INTERMITTENT FEVER.

By W. P. LATTIMORE, M.D.

THE discovery of some agent capable of serving as a substitute for Peruvian bark, or for its active principle, quinia, in the treatment of intermittent fever, has long been desired, in consequence of the high price of the sulphate of quinine, and the great adulteration of the salt to which this has given rise. The amount paid for quinine alone, is no small item in the annual expenses of the country physician; and this is likely to be increased, as it is said that a company of English druggists have monopolized the entire crop of Peruvian bark for many years to come.

In view of the interest necessarily felt in this subject, we have thought it might not prove uninteresting to the readers of the *American Journal*, to give the results of investigations made by the eccentric Piorry, upon the use of common salt in the treatment of intermittent fever. The investigations were commenced at La Pitié, and continued at La Charité, where they were witnessed by the writer.

The attention of M. Piorry was drawn to the subject by a memoir, presented to the French Academy of Medicine, in July, 1850, by Dr. Scelle Montdezert, entitled, "Practical Considerations upon the Treatment of Intermittent Fevers, and upon the mode of action of the Salts of Quinia, and of the Chloride of Sodium."

In this memoir, M. Scelle Montdezert supposes that every paroxysmal fever is due to the presence of fibrin in the venous blood; this fluid, in the normal state, being deprived of fibrin by the process of assimilation. That the salts of quinia owe their efficacy as anti-periodics to the fact that they dissolve this fibrin abnormally present, thus restoring the venous blood to its normal conditions. In casting about, then, for a substitute, he saw that Nature had largely disseminated both potassa and soda, each possessing, in a remarkable degree, solvent properties. Seeking, among the various combinations of each, that one which, uniting with the divers elements of the blood, should furnish the fewest insoluble compounds, he naturally selected the chloride of sodium, which forms none. He administered it, and then goes on to say:—"On account of these considerations we experimented without fear of injury, and we declare with satisfaction that the results of its employment are such that salt may now be considered as sharing with the salts of quinia the prerogative of arresting the paroxysms of intermittent fever. It is sufficient to administer half an ounce of it in the morning, before eating, during the apyrexia, in half a glass of infusion of coffee. Its use should be continued for three days. Fortunate results, observed during several years, have confirmed our foresight. It is a counter-proof of our opinion, long since emitted upon the action of the sulphate of

quinine, and one which gives the most satisfactory solution of this therapeutical problem."
